AMERICAN AGRICULTURIST,

FOR THE

Farm, Garden, and Household.

"AGRICULTURE IS THE MOST HEALTHFUL, MOST USEFUL, AND MOST NOBLE EMPLOYMENT OF MAN."—WASHINGTON.

ORANGE JUDD, A.M., EDITOR AND PROPRIETOR. | ESTABLISHED IN 1842. | $1.00 PER ANNUM, IN ADVANCE SINGLE NUMBER, 10 CENTS.

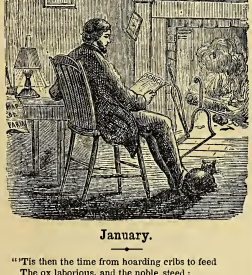
VOLUME XXI—No. 1. | NEW-YORK, JANUARY, 1862. | NEW SERIES—No. 180.

☞ Office at 41 Park-Row, (Times Buildings).
☞ Contents, Terms, &c., on pp. 29-32.

Entered according to act of Congress in the year 1861, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York. ☞ N. B.—Every Journal is invited freely to copy any desirable articles, *if* each article or illustration copied, be duly accredited to the *American Agriculturist.*

American Agriculturist in German.

The AMERICAN AGRICULTURIST is published in both the English and German Languages. Both Editions are of the same size, and contain, as nearly as possible, the same Articles and Illustrations. The German Edition is furnished at the same rates as the English, singly or in clubs. A club may be part English, and part German.



January.

"'Tis then the time from hoarding cribs to feed
The ox laborious, and the noble steed;
'Tis then the time to tend the bleating fold,
To strew with litter, and to fence from cold;
The cattle fed, the fuel piled within,
At setting day the blissful hours begin,
'Tis then, sole owner of his little cot,
The farmer feels his independent lot;
Hears with the crackling blaze that lights the wall,
The voice of gladness and of nature call;
Beholds his children play, their mother smile,
And tastes with them the fruit of Summer's toil."
HUMPHREYS.

The new year will, we trust, open not so badly, as some anticipated. There has, indeed, been calamity among merchants, some failures, and a great taking in of sail all around, some distress and short work among manufacturers in the early part of the year, but good prospects at the close. We shall always be a trading people, doubtless, but henceforth, we are to make more of our own goods. The debt being incurred by the war indicates a high tariff for many years to come. Almost every thing raised upon the farm, has ruled lower, but the demand has been steady, and the pay fair, especially for grain. Immense quantities of European gold have come into the country—more, probably, than ever flowed hither in a single year before, and it is now lining the farmer's pocket. He has the metal in his purse, and with many it is entirely a new sensation. The farmer was never more encouraged in his work. Manufacturers will be brisk supplying the hungry market, when the war is over, and that will make a brisk demand for all the farmer's crops near home. The world must have breadstuffs, fruits, beef, pork, cheese, and butter, and while grass grows and water runs, farmers can raise them.

Farmer Hardy is meditating upon these things, as he sits by his Winter fire, after the day's work is done. You see the blaze of his hickory wood, the lamp upon his table, the pile of agricultural books and papers, the pen and inkstand, and the cat purring and dozing at his feet. Like a sensible man, he does not keep dogs—does not believe in them—but believes in sheep. You see he looks amazingly comfortable, though a snow storm is raging without. What does he care. He is PLANNING THE CAMPAIGN for next season. You see farmer Hardy is a middle aged man, and has a good deal of experience in cultivating the soil. He has a great many proverbs at his tongue's end, and you can not talk with him five minutes without hearing some of these pithy sayings. One of these is, "*take time by the forelock.*" He is doing that now, and making all his arrangements for the whole year. He has learned that he can raise better crops, and make money faster, by laying out his work beforehand. He finds that his brain work by lamp light pays well in connection with the work of the muscles in the corn field, or in the meadow. He has a map of his farm, with every fence, gate-way, pond hole, muck swamp, orchard, and woodland laid down. He knows the enemies he has to contend with—rocks, water, brush, weeds, vermin, and how to marshal his forces, so as to overcome them. He is getting his guns and ammunition ready, and drilling his forces for the great struggle next Spring, and Summer. This planning decides between profit and loss, defeat and victory, in the year's operations.

He has no fields that are growing poorer, and running out. He enlarges his plans a little every year, and finds that the soil honors all drafts that he makes upon it. Another of his pithy sayings is, "*more manure,*" and you will find he has planned to make seven hundred loads this year. He wants five hundred for his hoed crops, and two hundred to spread upon his grass land in the Fall and Winter. He will make one hundred in the sty, two hundred in compost heaps out where he is to plant corn, and four hundred in his barn cellar and yard. This involves the carting of a good deal of muck and peat, of which he has always on hand a large quantity, dug a year before. When the ground is frozen, and the wheeling is good, his teams are all busy with the carting. When it rains or snows he has always work on hand in the barn cellar, or under the sheds, spreading muck and making compost. He hires his laborers by the year, so that they are never out of a job, and have no time to learn bad habits at the store or tavern. There is no difficulty with him in planning profitable work all the while.

He has been increasing the quantity of manure to the acre for several years, and finds he has not reached the limit of profit at fifty loads to the acre. He began with twenty loads, and finds that his corn costs less per bushel with fifty loads, than with twenty. Having five hundred loads of manure for plowed land, he will plant only ten acres to corn, but will get about eighty bushels to the acre.

Farmer Hardy has waked up to the value of roots, the last two years, and he has laid out two acres for field beets and carrots. Cattle do much better upon a variety of food, and a few roots every day give a relish to every thing else, and help digestion. He will tell you "*the proof of the pudding is in the eating,*" and point to his cattle as standing arguments in favor of root culture. Tell him that roots are "nothing but water," and he will answer you, "they are beef, veal, milk, butter, and cheese."

He not only goes in for manure and roots, but for draining land now useless. He has been draining swales and wet land, for ten years, and has now several miles of tiles and stone drains earning money for him under ground. He finds nothing like them to rout the enemy, water, and to make manure tell. His Winter grain is not winter-killed, on drained fields, and the grass is much heavier, and lasts longer. He is marking another field for drainage this year.

Another of his proverbs is, "*like produces like,*" and you will find he is making out a list of seeds now, for the field and garden. He knows what he has saved pure, and what he must buy, to get the best results from the season's campaign. He carries this maxim into his stock, and by judicious selection, has added twenty per cent to the annual yield of his cows, in butter and cheese. He has improved breeds of cattle, cows, sheep and oxen, pigs and poultry. He takes prizes at the fairs, and feels comfortable.

Farmer Hardy, with his planning and thinking these stormy winter nights, is a thriving, happy man. He never has a bit of the blues, for he knows just how he stands with the world, and how much he adds to his capital every year. He is not scared by gloomy prospects in the future, poor crops, winter-kill, cattle disease, or heavy taxes for the war. He knows that he makes his campaigning pay against rocks, weeds, water, brush, and other foes, and has no doubt that Uncle Sam is smart enough to vanquish all his enemies, and gain money and muscle by the exercise. With these comfortable convictions for himself and his country, he is likely to have the HAPPY NEW YEAR, with which we cordially salute all our readers.

Calendar of Operations for Jan., 1862.

[A glance over a table like the following will generally call to mind some piece of work that would otherwise be forgotten or neglected. The remarks are more especially adapted to places between 38° to 45°; but will be equally applicable further North and South, by allowing for latitude. —The calendar will, of course, be much more full during the season of active field and garden work.]

Farm.

Winter is the Farmer's seed-time for ideas. When the labors of the year press, and the mind is oppressed with the daily and hourly details of farm work, and the management of hands, many an idea occurs to one which he must wait until Winter to develop and inform himself upon. His mind may then be freshly enriched from books and contact with other minds, and is in a fit state for the profitable development of the thought-germs gathered during his season of labor.

Agricultural Reading—Place at least one good farmer's paper, better three or four, upon your center table in the sitting room. Encourage every member of the family to read. Keep a pleasant fire, bright light and quiet there, so that every one may read who will. The little it costs will be a most profitable investment. Buy rather those books which treat thoroughly of one subject, than those which profess to contain a little of almost every thing in small compass.

Barns—Protect roots against frost, if you have them stored in the barn cellar. Pack the hydrant in strawy horse manure, which is best done by placing a headless barrel around it and then filling that. Look out for slippery spots in the cattle walks, and especially near gates or doorways; cover the ice with earth or ashes, but never put on salt—unless you remove it *all*. Now, if ever, should every thing be in its place and the whole barn neat and clean.

Cattle—Feed no more than you can keep well. Give good bedding to all. Keep milch cows and fatting cattle still; they need little or no exercise. Young stock and working oxen should spend some hours daily in the open air unless it is very stormy, but when stabled, should be warm and comfortable. Never feed on the ground, but in racks. Cattle kept in yards, (a poor practice at best) should have roomy and warm sheds. Provide if you can lumps of rock salt for cattle to lick when they please, otherwise, salt them once a week. If you suspect lice, rub a little unguentum (mercurial ointment) mixed with lard, behind the horns, and tie up for some days. Feed roots finely sliced; turnips first, beets, mangels, and ruta bagas by and by. Beef animals need the assiduous care of the *owner* now more than at any other season.

Cellars—Air well on warm, moist days. Keep clean and watch the appearance of fresh rat holes, all of which close with broken bottles and cement mortar.

Dairy—Color winter butter with carrots fed to the cows.

Eaves and Eave-spouts—Clear of leaves, etc., on thawing days, if not done, that the cistern may not lack water.

Farmers Club—Start one at once, if you have not one now, and attend one at any rate if there are not more than three members. Have no secrets, the smallest kind of men have the most.

Fencing stuff—Get out, and haul when you have good sledding, at least a third more than you think you can use.

Fodder—Cut up coarse fodder, wet it, salt it, sprinkle enough oil-meal or slip-stuff on to give it flavor, and let it stand, stirring occasionally till well soaked and mixed. All kinds of stock will eat it. Use no worthless fodder except in the manure heap.

Frost—Sprinkle a handful or two of salt around posts likely to be heaved by the frost, picking out the ice to the ground, in a little groove close to the post. What ever is frozen and liable to injury by frost, thaw very slowly; put vegetables or apples into *ice cold* water.

Fuel—Cut fuel without stint, and be ready to haul what is cut as soon as there is fair sledding.

Granary—Thrash and get all grain into an airy, dry, rat proof granary as soon as possible. Many a farmer loses enough grain by rats and mice to winter a horse. Mice and rats multiply rapidly if they have anything to live upon—employ all help to get rid of them. A cat is an excellent thing in the barn, but keep her out of the granary, unless she is very well colored. Corn keeps best on the ear; if it is to be fed out this Winter *shell* it as soon as you please; if you are to keep it into the Summer leave it on the ear.

Hemp—Break, and bale up for market in dry weather, this month and next.

Horses—Keep well shod and sharp. Be very careful to blanket horses when they are warm. Give liberal bedding, and the best of care to the breeding mares, taking special care that they do not fall in slippery weather, if long with foal. Break colts, and subdue fractious colts or other horses by the Rarey method, when there is a foot of soft snow on the ground. Feed carrots in small quantities, 4 quarts a day, to all classes of horses.

Harnesses—After being wet, wipe and oil them thoroughly before they dry. Have all harnesses overhauled, and put in good order.

Ice—Get out ice in the coldest weather for then it is dry. Set the cakes on their edges, and if possible pack them in the ice house in early morning when the temperature is near or below zero. The first formed ice is best.

Implements—Think up what new ones you want, and find out which are the best kinds.

Manure—Make it under cover. Do not let it freeze even, if it can be helped. This is the manure harvest and as much should be gathered as possible. Compost with muck or earth. Save *all* the liquid manure, and every thing about the house or barn that has the principle of decay in it. Keep the manure heap moist, compact and level. If it touches the outside of any building clear it away at once, smooth over the scars, and apply grafting wax or waxed cloth to keep out the rain from cracks.

Market produce as soon as there is good sleighing or hard roads; prices are now somewhat remunerative. Look up various kinds of manufacturers' wastes leather chips, etc., for return loads. Sell grain by sample, warranted, with the privilege of delivering it at your own time, if you can do so.

Plowing—We can occasionally do some plowing in January. Do it if you can make good work.

Poultry—Give them warm, dry, sunny, well whitewashed quarters, clean straw in the nests, a good feed of grain once a day, and once a day boiled and mashed potatoes and scraps from the table, with occasionally "scraps" from the frying pot too, and *unchilled water*, or a trough of running water to drink and you will not lack eggs. Keep an ash box in one corner always dry and dusty, and throw in fresh ashes or lime now and then.

Roads and Paths—Open the roads after snow storms. Out upon the man who lets his neighbors open his road for him! A snow plow for one or two horses after every snow should draw its furrows 4 feet wide through the whole neighborhood, and thus neighborly intercourse will be established, the children can go to school, and the women can get out to the prayer meeting, which otherwise might be for several days.

Sheep—If sheep have good shelter they "know enough to come in when it rains." Never expose them, give them the range of a good large yard—not of the open field—fold them nights, let the buck run with the ewes now for June lambs. Give fatting sheep most careful attention. Watch the first symptoms of disease.

Sink drains, etc., are apt to freeze up—prevent it.

Swine—Fat hogs should have been killed and packed or marketed last month. If that job is still on your hands have it done with at once. Keep growing pigs at work in the manure heap—and encourage activity with an occasional handful of corn. Give breeding sows warm nests, plenty of litter, and good feed, but not of a fattening character. Send sows to the boar for May pigs.

Timber, Wood lots—Do not cut trees so as to leave tall stumps. Cut with reference to young and growing trees. If you have timber or bark to draw out from swampy ground, employ the first opportunity after the ice will bear your team.

Tools if not greased will be likely to rust; attend to this, and to any repairs they may need. Make up a lot of rake teeth, and hay caps, and other things which you will need next Spring or Summer.

Orchard and Nursery.

The present month offers to nurserymen and orchardists an opportunity to put things to rights; to fit up buildings conveniently, and to do many things about their places which they will neglect, or half do in the hurrying season, when the frost is leaving the ground, and customers are clamorous for trees.

Grafting—Root-graft young trees in-doors,—best in a good cellar, where neither grafts nor roots will dry. Never graft on *pieces* of root.

Implements are to be renewed; provide a good stock, mending old and purchasing new ones.

Insects—The eggs of certain insects laid upon the bark are easily discovered now. Let no good orchardist fail to make himself acquainted with them, and destroy as many as he can. Read Fitch's Reports. In warm weather the wingless millers of the cankerworm come from the earth, and should be destroyed.

Labels—Provide an abundance both of wood and zinc. Lead labels are very convenient for the orchard, and may be cut and stamped with numbers or names at this season.

Mice—Stamp down snow close about trees in young orchards—or otherwise defend them against depredation.

Scions may be cut whenever we have a warm "spell," bury them in slightly moist earth or sand—not moister than good soil in Summer; tie up and label accurately.

Surface Drainage—Hard rains coming upon partially frozen ground often do great damage by washing off the surface, if good superficial drainage is not provided.

Stakes—Work out new, to supply the place of those which failed last year. Make them stout and of good stuff, and by all means soak them in a solution of a pound of blue vitriol to 12 quarts of water. They will last five times as long.

Trees too large to be moved in Spring may be transplanted in Winter by digging about them so that the mass of earth in contact with the roots may become a frozen ball, 6, 8, or even 10 feet in diameter, and capable of being moved with the tree. Prune severely before moving, but leave the large limbs so that they may be cut again in Summer to secure well healing scars.

Winds—Tie up to prevent danger from winds when possible, and when it occurs, remove broken trees and branches at once, smooth over the scars, and apply grafting wax or waxed cloth to keep out the rain from cracks.

Kitchen and Fruit Garden.

Lay out spring work—with the vegetable gardener this often begins quite actively next month.

Cold Frames—In very cold weather give extra cover, but remove on warm, sunny days. A good blanket of light snow is worth more than any thing else. See that they do not get damp for want of ventilation, and rot the plants. Give light and air freely in warm weather.

Cuttings of Currants and Gooseberries may be taken in mild weather, and stored in sand. See page 19.

Draining may be pushed in open weather, whenever, indeed, there is neither too much frost nor too much water in the soil. See full chapters in last volume.

Grape Vines, if not already pruned and laid down, may now be attended to. Protect by covering with hemlock boughs. Never handle them while frozen.

Mushrooms—Prepare beds in any place free from frost.

Poles and Pea-brush—Cut and prepare for use, stacking them under cover. It pays well to soak the ends, if not the whole of bean poles in blue vitriol water to preserve them.

Prune fruit trees with the *knife only* this month.

Rhubarb—Force, last of the month, by heaping strawy and heating manure over the crowns; protect well if the weather afterward becomes severe.

Seeds—Buy in time to test every doubtful sample; it saves vexation and many dollars. It is best done by counting the seeds and sowing them in good soil in pots kept under hand glasses, in a warm place, and counting the number that germinate.

Vegetables in the cellar will continue to arrive at perfection, and need care only that they do not freeze or rot. Let them have air on warm days.

Flower Garden and Lawn.

The time is invaluable for reading and getting information. There is little to be done. After, or during heavy snow storms, shake the snow from the evergreens and other trees loaded with it. In warm weather, if the frost is coming out, let the rose pits, (cold pits under sashes where half-hardy plants are kept,) without letting in the sun; so long as they remain frozen, let them alone. The frost can seldom be entirely excluded. If the earth in the pots becomes *very dry*, give a very little water.

When the frost is out of the ground, deep spading brings insect pupæ to the surface, and they are thus destroyed in great numbers. Give the fowls a chance at them if you can.

Borders not yet protected may be covered with light strawy manure, leaves, evergreen boughs or the like. It seldom happens that injury occurs to half-hardy plants of any kind before the "January thaw," or other period of continued warm weather.

Green-House.

Keep the temperature below 60°, and if possible above 35°. Plants which will not bear the least frost, ought not to be kept in a Green-house adapted to oranges, lemons, oleanders, camellias, myrtles, azaleas, roses, etc. Give good ventilation on mild days, and water sparingly, always with reference to the state of the plant, increasing water, warmth, and light, when it begins to grow, or approaches blooming. In the green-house force nothing. Stir the soil in the pots and remove dead leaves. If lice appear, make all tight, smoke thoroughly, and syringe affected plants afterward. When oranges and lemons begin to grow, wash stems with strong soap-suds and crush scale insects.

Protect by mats or shutters on cold nights, and more than all else avoid dampness.

Bulbs—Tulips, hyacinths, crocuses, etc., etc. Pot and keep in the dark and away from the heat till well started; water freely. Hyacinths in glasses or moss, should be treated in the same way. Start them slowly. If already growing, remove them to the hot-house or conservatory.

The description of a "Sixty Dollar Green-House," on page 20 (of this number), will be found worthy the attention of a great number of our readers. Such a house will afford room to start a great number of plants, for transplanting early to the garden.

Hot-House and Conservatory.

In the Hot-house flowering and ornamental plants are propagated and brought to perfection; and in the Conservatory they are placed for show and to minister directly to the enjoyment of the family and guests. Here maintain an atmosphere of uniform moisture and warmth—never allow a drying heat, a scorching sun, or frost. Sprinkle freely those plants whose blossoms are not injured by water. Use, occasionally, liquid manure quite dilute, until plants begin to stop blooming. It gives them vigor, and they feel the change from the hot-house less. Keep growing plants close to the light, and turn frequently. Remove plants at once when their beauty has gone, when they begin to grow much, or when you discover insects or mildew.

Hot-house — Avoid extremes of temperature; this must be graduated according to the class of plants, the degree of forcing, amount of moisture, etc. Admit air through the upper ventilators to avoid drafts.

Cuttings of various plants may now be profitably started, viz: roses, verbenas, petunias, fuchsias, geraniums and the like. See page 19.

All growing plants and those coming into bloom require much moisture, and all the light they can have. Water regularly, sprinkle frequently, but avoid excess.

Pines require the warmest and moistest atmosphere, and should have a separate house or room. Cucumbers force admirably in the same apartment at this season.

Look out for insects; use sulphur for red spider, tobacco smoke for aphides and thrips, tobacco water and soap-suds for scale-bugs, etc.

Keep the soil in pots stirred, and shift growing plants so often that they will receive no check.

Grapery and Orchard-House.

Cold Graperies and Orchard-Houses will need no attention this month, except to maintain them at a uniform and moderately low temperature, and guard against dampness and injury from mice. If there is danger from dampness lay lumps of quick-lime about, say a bushel lump under each vine or tree. In houses where a moderate heat is employed, it is still early to lift the vines, and prepare the trees for fruiting, except where a succession of crops is desired; in this case, for the earliest crop, lift the vines, tie them to the rafters, and give inside borders or tubs a good watering with liquid manure; increase the heat and keep it at 45 to 50°—seldom higher—never let it fall to freezing; dampen the floor and wall by sprinkling.

Peaches and Apricots—Treat much the same as above. They will bloom in 15 to 20 days.

In forcing houses, the vines and fruit trees may be in any or all stages of development, and it is impossible to give particular rules; they demand the constant thought and care of the gardener.

Mildew—Whenever mildew appears syringe with water containing sulphur, or lay sulphur on the brick flues.

Apiary in January.

Prepared by M. Quinby—by request.

Bees properly housed, need but little attention; an occasional examination to see that all is right may be made, going among them quietly that they be not unnecessarily disturbed. If mice or rats have found their way into the hives, it may be known by the combs having been nibbled. Traps temptingly baited, seem to be the best remedy. It would be dangerous to use poison to destroy them, as it might be communicated to the honey.....Stocks standing in the open air, when secure from the mice, may be covered with snow through all the severe weather. It will effectually protect the bees from frost. If the hive is only partially covered, or a little around the bottom, it should be removed, keeping the air passages free. Ice, snow, or wood often accumulate about the entrance and smother the bees. In severe weather, allow the sun to strike the hive. When just moderate enough to tempt the bees out, and cool enough to chill them before they return, shade the hive by setting a wide board before it. When the day is very fine, allow them to fly, except in case of new fallen snow. If the frost at any time leaves the hive, it may be raised and all dead bees and filth brushed out. When all is right, do not disturb them in severe weather.

Seeds for Free Distribution to all Subscribers for 1862 (Vol. 21.).

Keery subscriber to the Agriculturist for 1862, is invited to select four or five packets of seeds from the list below.

These seeds are all valuable. Of the 90 kinds offered, many are *new* varieties, but we include several common useful sorts for the convenience of those living remote from access to good seeds.

Most of them are annuals (reproducing seed the first season), and in all cases there will be enough to yield a good supply for future use. Our aim is, to furnish the germs of future abundance in each locality where these seeds go.

Many of these seeds have been grown by ourselves, the past year; the others are obtained of the best growers in this country and Europe. The distribution will begin early in February. A description is given in the next columns.

Mode of Distribution.—The seeds may be called for at the office after Feb. 10, or be applied for by mail at any time; they to be forwarded when ready. The postage is only **1 cent per ounce under 1500 miles; and 2 cents per ounce when over 1500 miles.**

Those sending for seeds to be forwarded by mail, will please *carefully* observe the following

DIRECTIONS—(1). Select from the list below, any four or five parcels desired, and write *plainly* on a slip of paper the *numbers* and *kind* of the kinds of seeds wanted. Certain numbers are used on our seed drawers, seed bags, etc.)

(2) Enclose the slip in a prepared envelope—printed in full to your own address, as here shown, and put upon it postage stamps to the amount of **one cent** *for* **each ounce** *of seeds to be enclosed*, if to go **under 1500 miles**, or **two cents** if to go **over 1500 miles.** (Most places East of the Mississippi river are over 1500 miles.) **N.B.**—The total amount of stamps required can be reckoned from the table of seeds below. Any fraction over even ounces will need an extra 1c. or two 1-cent stamps according to distance. Forward the above prepared envelopes to this office, and the seeds will be enclosed therein, and to the numbers on the enclosed slip. To save letter postage, let there be *no marks on the enclosed envelope* but the number of stamps. About 3 ounces will go in a common sized envelope.

John Smith,
Illinois.
Monroe County.

Field, and Vegetable Garden Seeds.

No.		Weight of package.
183	Mammoth Long Bearded Spring Wheat	1 pound.
3	Improved King Philip Corn	One or two ounces.
141	Mammoth Early Sweet Corn	About one ounce.
186	Evergreen Sweet Corn	About one ounce.
98	Long Red Mangel Wurtzel	About one ounce.
187	Com. Broad Leaf Tobacco	About one-eighth ounce.
188	Connecticut Seed Tobacco	About one-eighth ounce.
191	Mammoth Millet	About one-half ounce.
189	Common Spring Wheat	About one ounce.
190	Negard Barley	About one ounce.
5	Daniel O'Rourke Pea	About one ounce.
9	Champion of England Pea	About one ounce.
99	Prince Albert Pea	About one ounce.
12	Early Red Flat Turnip	About one-fourth ounce.
13	Fulfield Market Cabbage	About one-fourth ounce.
143	Early Purple (Vienna) Kohl Rabi	About one-fourth ounce.
192	Improved Stonemason Cabbage	...one-fourth ounce.
193	Red Dutch Cabbage	About one-fourth ounce.
64	Extra early Round Turnip Radish	one-fourth ounce.
150	Early Purple Cape Cauliflower	About one-fourth ounce.
147	Neapolitan Cabbage Lettuce	About one-fourth ounce.
73	Imperial Brussels Sprouts	About one-eighth ounce.
101	Improved Long Orange Carrot	About one-half ounce.
148	Long Blood Beet	About one-half ounce.
149	Extra early Bassano Beet	About one-half ounce.
85	Hubbard Squash, pure	About one-fourth ounce.
193	Fejee & Italian Red Tomato	About one-eighth ounce.
154	Ice-cream White Egg Tomato	About one-eighth ounce.
7	Improved Netted Musk Melon	About one-fourth ounce.
194	Hollow Crown Parsnip	About one-fourth ounce.
96	Curled Parsley	About one-fourth ounce.
151	Yellow Danvers Onion	About one-fourth ounce.
152	Large Cheese Pumpkin	About one-eighth ounce.
17	Best Strap-Leaf Turnip	About one-fourth ounce.
71	Long White French Turnip	About one-half ounce.
195	Early Short Horn Carrot	About one-fourth ounce.
102	Early Mohawk Bean	About one-half ounce.
103	Sage	About one-eighth ounce.
196	Summer Savory	About one-eighth ounce.
157	Long Prickly Cucumber	About one-eighth ounce.
166	Green Curled Kale	About one-fourth ounce.
198	Improved Purple Egg Plant	About one-eighth ounce.
24	Wilson's Cherry	About one-eighth ounce.
197	Linnæus Rhubarb	About one-half ounce.

Flower and Ornamental Seeds.

89	Cotton Plant (2 kinds, mixed)	One-half ounce.
114	Castor Oil Bean	One-half ounce.

On an average any **five** *of the following varieties will go under one 1-cent stamp, (or two stamps if over 1500 miles.)*

200	Fancy Gourds, (mixed	212	Pine Sweet Peas, (hh.)
201	Scarlet Chinese Egg Gourd	124	Whitlavia, (hh.)
202	Animated Oats, (hh.)	213	Cardytah, (hh.)
177	Quaking Grass, (a.h.)	214	Balloon Vine, (hh.)
203	Mixed Nasturtium, (hh.)	183	Sweet Alyssum, (hh.)
204	Mixed Sweet Peas, (hh.)	215	Eccremocarpus Vine, (hh.)
33	Portulacca Mix'd, (hh.)	175	Mixed Salpiglossis (hh.)
31	Phlox Drummondii, (hh.)	216	Acroclinum Roseum, (hh.)
205	Double French Marigold, (hh.)	50	Mixed Schizanthus, (hh.)
206	Golden Straw Flower, (everlasting) (hh.)	49	Eschscholtia Californiea, (hh.)
208	Crimson Globe Amaranth, (everlasting) (hh.)	213	Xeranthemum Annum (hh.)
210	Convolvulus Tricolor, (hh.)	125	Standing Cypress, (h)
173	Mixed Larkspur, (hh.)	43	Foxglove, (hh.)
107	Malope Grandiflora, (hh.)	209	Dwarf Blue Larkspur, (hp.)
211	Fine Mixed Lupins, (hh.)	171	Forget-Me-Nots, (hh.)
215	Eccremocarpus Vine, (p.)	127	Long tubed Centranthus, (hh.)
216	Acroclinum Roseum, (hh.)	214	Balloon Vine, (hh.)
213	Xeranthemum Annum (hh.)	125	Standing Cypress, (h)
126	Long tubed Centranthus, (hh.)	43	Foxglove, (hh.)
214	Balloon Vine, (hh.)	209	Dwarf Blue Larkspur, (hp.)
125	Standing Cypress, (h)	171	Forget-Me-Nots, (hh.)
43	Foxglove, (hh.)	215	Eccremocarpus Vine, (p.)
209	Dwarf Blue Larkspur, (hp.)	127	Long tubed Centranthus, (hh.)
171	Forget-Me-Nots, (hh.)	216	Acroclinum Roseum, (hh.)

* (hh.) hardy annual; (hh.), half hardy annual; (h), tender annual; (hh.), half hardy biennial; (h), tender biennial; (hp.), hardy perennial; (hhp.) half hardy perennial; (p.), tender perennial.

Descriptive Notes upon the Seeds in our List for free Distribution in 1862.

We devote considerable space to a condensed description of the 90 varieties of seeds named in the preceding column. These notes will afford some information upon the character and cultivation of the several plants, where ever the seeds may be obtained, and they should be preserved for reference in the Spring planting season More full directions for the culture of these and other plants will, of course, be given from time to time, in separate articles. The Calendar of Operations, from month to month, will also suggest the time of sowing or planting. Most of the field seeds are necessarily in too small quantity for a crop, but with a little care in culture each parcel will produce a fair supply for a good sized crop the next year. Our seeds will not be ready for distribution at all before the first or second week in February, of which information will be given in the next paper. But we desire to now get in all applications (as per preceding columns) at the earliest moment possible, that we may be able to arrange the supply in proportion to the demand.

For brevity, the *Numbers* are always used in putting up and sending out seeds, and subscribers are particularly desired to note this in their application. To avoid confusion, we use a new number for each addition, dropping the numbers of any seeds previously offered, but not retained in this list. The additions of the present year number from 183 to 215, all the seeds numbering from 2 to 183 belonging to previous lists.

Field and Garden Seeds.

No. 2.—Improved King Philip Corn.—A rapid growing, 8-rowed sort, larger than the old King Philip, both in the stalks and in the ears; when pure, of deep brown color and heavy. It ripens with us in 95 to 100 days from planting—in drills scant 3 feet apart, and kernels dropped 10 inches asunder. We have been so pleased with it in the previous two years that we last Spring planted **3 acres** for this year's distribution. It may be planted later than the common varieties and further north.

No. 8.—Daniel O'Rourke Pea.—An early sort of fair quality, grows 2 feet high, and may be eaten in 40 to 45 days from planting. Sow from first to last of April, according to climate, or any time in May to multiply seed.

No. 9.—Champion of England Pea.—A later, tall-growing variety. We want nothing better than this sort, which is our chief dependence for a table pea through the season. Sow as No. 8, or at intervals until middle of July, if seed is plenty.

No. 12.—Green Whole Kabi, or Cabbage Turnip.—The bulb, which resembles a turnip, grows above ground like a cabbage. Plant early in May, the same as turnips, and for table use boil the bulbs when still tender. They acquire a toughness if kept till Winter. This is coming largely into use for cattle and sheep, in England.

No. 13.—Enfield Market Cabbage.—We have already distributed this 3 years, and it is liked so well that we offer it again. It is a quick-growing sugar-loaf variety, sweet and tender. Sow in hot-beds early in April, or in open ground the last of April or early in May, and plant out 18 inches apart, in the rows.

No. 17.—Red Strap Leaf Turnip.—A very quick growing variety of the flat or Dutch species, with a red-dish or purple top. They are good for the table, while growing, and for stock during Autumn and early Winter. Sow with drills from the first of April to September.

No. 21.—Winter Cherry (*Physalis viscosa*).—Called also, Ground Cherry, Cape Gooseberry, etc. This grows wild in some places, but not so large fruit as when in cultivated soil. The fruit grows in capsules, is about the size of common cherries, when ripe is liked by many persons, eaten raw, and makes a fine preserve if done up with a little sugar and some lemon juice. The fruit will keep through the Winter in any cool room. We grow it every year, and it is so well adapted to new countries where there is no other fruit, that we replace it in the seed list. Sow early in Spring, the earlier the better, as the seed frequently lies in the ground until June. When once started it grows rapidly, and a single plant covers four to five feet in diameter, in rich soil.

No. 64.—Early Turnip Radish.—A quick-growing round sort, crisp and sweet. Sow at any time after frost is out in Spring, and at intervals until September. If the early sowings are allowed to go to seed, a second crop may be raised from this seed the same season. It always reproduces seed the first year.

No. 65.—Curled Parsley.—Sow at any time in May,

for Summer use, or in August for transplanting to cold frames or boxes for Winter. Cover lightly with fine earth.

No. 71.—Long White French Turnip.—This is of the form of the rutabaga, but is white, very fine, sweet flavor. May be sown at all seasons for table use. For Winter use and feeding, sow early in July, and during the month.

No. 72.—Brussels Sprouts.—Button cabbages, growing singly or in clusters upon a cabbage stump. Sow and cultivate as cabbages, using the small heads for boiling. They are more delicate than ordinary cabbages.

No. 74.—Solid White Celery.—Sow in hot-bed in April for early or in open ground during May or June for late crop. See chapter in type for this or the next *Agriculturist*. The blanched stalks are eaten raw, with meats, etc.

No. 76.—Skillman's Netted Muskmelon.—So called from its rough skin. A round, sweet, and rich sort, with green flesh. Plant as Watermelons.

No. 95.—Hubbard Squash.—The best *Winter* squash we have tried. Keeps until Spring. Plant middle of May. Color dark green to light blue, hard shell, with rich dry flesh. It is also good for Autumn use.

No. 96.—Long Red Mangel Wurzel.—A large stock beet, sometimes reaching 15 to 20 lbs. in weight. It is much raised in England, and is valued highly for feeding. Produces immense crops, from 25 to 30 tuns per acre. A Connecticut correspondent, (page 362 Vol. 19) reported 36 tuns or 7200 bushels on an acre. Sow last of April, or early in May, on a deep rich soil, in drills 2 feet apart, and when well up thin to 1 foot in the row.

No. 99.—Prince Albert Pea.—An early English sort, growing about 3 feet high. Has proved very good with us, in two years' trial. Sow same as No. 8.

No. 101.—Improved Orange Carrots.—A fine yellow variety, suitable for the table or for stock. Sow early in May, on deep, rich soil, in rows 15 to 18 inches apart.

No. 102.—Sage.—A small bed should be in every garden. Sow at any time in May, in rows one foot or more apart, covering less than half an inch. The perennial roots will yield two pickings each season.

No. 141.—Darling's Early Sweet Corn.—We have tried many other early sorts, but come back to this, as combining sweetness, and rapid maturity. It is quite small in stalk and ear, and may be planted in hills or drills 2 to 2½ feet apart, unless other crops are put between the rows to occupy the ground after this is out of the way, which will be before mid-summer if planted early. It may be planted all Summer for a succession, among early cabbages or potatoes.

No. 145.—Flat Dutch Cabbage.—A Winter sort, extensively grown for market, frequently under the name of "drumhead." The heads are large, and require to be 2 feet apart, in 2½ feet rows.

No. 147.—Neapolitan Cabbage Lettuce.—A large solid sort, which has proved valuable. Sow at any time in April, May, or June, covering lightly. Leave sufficient plants for seed, which is reproduced the first season.

No. 149.—Early Bassano Beet.—A fine, quick growing, turnip shaped sort, for early use. Sow in drills one foot apart.

No. 150.—Early Paris Cauliflower.—One of the best sorts. Has a white, solid flower. It has given good satisfaction to most of those who have received it from our former distributions, and we reintroduce it—knowing nothing better. Sow and treat every way as cabbages.

No. 151.—Yellow Danvers Onion.—A large, flat onion which commands the highest market price. Sow last of April on a warm soil in rows 10 to 12 inches apart, covering lightly.

No. 152.—Large Cheese Pumpkin.—Acknowledged the best for general culture. A large, flat, cream colored variety, sweet, and good keepers. Plant middle of May, allowing ample space for them to run.

No. 154.—Ice Cream Water Melon.—One of the best sorts, sweet and tender. Plant in open ground about the middle of May, and can be started earlier in hot-bed.

No. 156.—Summer Savory.—A well-known, and unusually aromatic herb. Sow in April or May; cover lightly.

No. 157.—Long Prickly Cucumber.—A much commended sort. Plant at any time in May or June and keep watch for striped bugs as for all cucumbers.

No. 184.—Long Blood Beet.—A good tender sort for the table during Autumn and Winter. Sow middle to last of May in light, deep soil, in rows 1½ foot apart.

No. 185.—Bearded Spring Wheat.—A very excellent wheat which we found growing in a field in Westchester Co., N. Y., last year. The berry was as plump and fair as the best of Winter Wheat, and the yield large. It seemed to be specially worthy of introduction and trial elsewhere. Our parcels, planted or sown in drills, in April or May 1st, will furnish a fair supply for next year.

No. 186.—Evergreen Sweet Corn.—A much larger variety than No. 141, a slower grower; not quite so sweet; remains in the milk state a long time, hence called evergreen. Good for later table use, and for fall drying. If to be ripened for seed, plant early; for table use, from May 15 to June 20, in hills or drills 3½ to 4 feet apart.

No. 187.—Connecticut Seed-Leaf Tobacco.—Offered in response to many inquiries. The seed is so small that it is better to mix it with earth or mold, and sprout it by keeping warm and moist for 2 or 3 days. A thimble full of seed will furnish plants for an acre. Sow in a sheltered seed-bed about the middle of April, and plant out middle of June, on rich dry soil, 3 feet apart each way, or 3½ feet by 2 feet to facilitate working with a horse hoe. For after treatment see future articles on Tobacco.

No. 188.—Havana Tobacco.—Treat as No. 187, save that it requires less room—say 2 feet each way. Keep the ground well stirred and free from weeds.

No. 189.—Spelt, or German Wheat, called also "Dinkel," is little known in this country; and, owing to numerous inquiries from our German subscribers, we have imported a quantity for distribution. Sow early in Spring, as ordinary Wheat. It will flourish on common soil. For a full description, see page 104, vol. 19.

No. 190.—Nepaul Barley.—A curious sort, illustrated on page 361, last volume (September No.). It puts from its hull the same as rye, and is said to yield a heavy crop. Sow early in May—in drills, to obtain the largest results from a little seed.

No. 191.—Mammoth Millet.—An annual, very productive in seed and foliage. Cut green, it makes good hay, or left to ripen, the straw is good, and the seed valuable for stock and poultry. Sow thinly half an inch deep, at any time in May.

No. 192.—Stone Mason Cabbage.—A solid cabbage, very good, of compact form, and keeps well. We tried it last year, and like it much. Sow and treat as No. 145.

No. 193.—Fejee and Italian Tomatoes.—Large, smooth and solid varieties, the best we have grown. Sow in hot-bed, April 1st for early, or first of May in open ground for later.

No. 194.—Hollow Crown Parsnep.—A large, long and sweet variety, with a depressed crown. Sow in deep, rich soil, early in May, in rows 18 inches apart, covering lightly. Best after being left in ground over Winter.

No. 195.—Early Short Horn Carrot.—A fine yellow variety for early table use. Sow in light soil last of April or first of May, in drills 1 foot apart, covering lightly.

No. 196.—Green Curled Kale or Borecole.—A kind of cabbage which does not head. The whole top is boiled for greens; usually in Spring, as it bears standing out over Winter, with (and often without) a slight covering of straw or brush. Sow from April to June, and treat the same as late cabbages.

No. 197.—Linnæus Rhubarb.—Sow in deep mellow soil in April or May, covering ½ inch. Keep well hoed, and transplant the following Spring when a few stems may be pulled for cooking. A full crop can not be had until the 3d year, on which account it is better to purchase and plant roots at once when they can be had. It furnishes a fine material for early sauce and pies, and should be in every garden.

No. 198.—Purple Egg Plant.—There are many fanciful sorts, but this is the most approved variety for general culture. Sow in a hot-bed, early in April and plant out 18 inches apart, the middle of May, or after all danger of frost is over. It is still better sown in, or transplanted into small pots, keeping them under glass till June, when the whole may be transfered to the soil, without disturbing the plants.

No. 199.—Red Dutch Cabbage.—Highly valued for pickling and for "cold slaw." Heads small, sugar loaf form, and solid. Set plants 15 to 18 inches apart each way. Its color is fancied by most persons.

Flower and Ornamental Seeds.

No. 23.—Mignonette (*Reseda odorata*)—An annual in this climate. The flowers not conspicous but yield a rich odor. Its habit is low, branching upon the ground; flowers profusely from midsummer until frost; may be potted for winter blooming. A great favorite. Sow as early as the ground can be worked—the seed is long in coming up.

No. 25.—Mixed Nasturtium (*Tropæolum majus, in var.*).—This peculiar plant is very showy in flower, and the fruit, a green capsule, is highly prized for pickling. The common varieties are rambling and delight to climb over fences, bricks, rough stone walls, etc. Others are dwarf and bushy. Sow in May and thin to one foot apart in single rows. Annual.

No. 27.—Cockscomb (*Celosia crestata.*)—A very curious and common annual, native of the East Indies. Flowers in fantastic, irregular spikes, inclining to the fan-shape, like the comb of the cock, and of the richest crimson color. Sow in rich soil, early, and thin to 18 inches apart.

No. 30.—Tassel Flower (*Cacalia coccinea*).—Called also "Venus Paint Brush." A delicately beautiful annual, growing 1 to 2 feet high, and blossoms freely. The scarlet flowers are little perfect tassels, very bright and pretty. Sow in May and thin out or transplant to 6 or 10 inches.

No. 31.—Chinese Pink (*Dianthus Sinensis*).—A very pretty little annual of this fine class, most of which are perennials treated like an annual. It is not fragrant like the Sweet William, nor does it grow in clusters. Color varies from maroon and crimson with pink edging, to white with a red center. They flower for many weeks in succession, and are desirable in every flower plot. Sow in early Spring. The roots frequently survive the Winter.

No. 32.—Portulaccas, mixed (*Portulacca splendens, in var.*).—Low growing annuals, fleshy leafed and spreading upon the ground like purslane. Flowers of various brilliant colors. May be sown at any time and will continue in flower, until cut down by frost.

No. 33.—Cypress Vine. (*Quamoclit vulgaris.*)—One of the finest annual climbers, with delicate feathery foliage and bright trumpet shaped flowers. It will climb a string or other support 12 to 18 feet in a season, and is a fine plant to train in a cone shape around a central stake. Soak the seed for 12 hours before sowing and only put it in when the ground is warm. Sow May 1st to June 1st, according to the locality.

No. 37.—Zinnias, (mixed) (*Zinnia elegans*).—This beautiful Mexican plant is a brilliant addition to the flower garden. It is tall, elegant and showy, with flowers of many colors, purple, crimson, orange, scarlet, violet and white. Sow middle of May, keep plants 18 inches apart.

No. 40.—Eschscholtzia (*E. californica.*)—Annual or biennial plants with orange-colored tulip-shaped flowers, very showy. Sow in May, or earlier, in hot-beds and transplant. Sometimes called California poppy.

No. 42.—Foxglove (*Digitalis alba, purpurea, etc.*).—A perennial, blooming the second year from seed. The flowers are very pretty, often beautifully mottled with purple and brown spots. They grow 2 to 4 feet high and flower upon a spike beginning at the bottom, and continue in bloom for several weeks. The medicine digitalis is obtained from the leaves and seed of this plant. Sow in early Spring. The roots often die out after flowering a year or two.

No. 49.—Candytuft (*Iberis umbellata, and amara.*)—Suitable for massing or for borders. An annual with clusters or umbels of small flowers, of various colors from pure white to purple. Grows 6 to 12 inches high, and blooms most of the season. Sow early in Spring.

No. 50.—Schizanthus (*S. pinnatus, in var.*).—Beautiful annuals, with yellow, purplish or scarlet flowers. Sow in May, or earlier, in open ground.

No. 51. Phlox Drummondi (*Phlox Drummondii.*)—A very beautiful annual, the delicate flowers of which exhibit a very great variety of marking. Grows 12 to 18 inches high, requires little care, blooms constantly and is beautiful in masses. Sow early in May.

No. 89.—Cotton Plant (*Gossypium herbaceum and hebadaticum*).—The Upland, with a little Sea Island Cotton Seed, both in the same package—the Upland downy, the Sea Island naked. The Upland, sown in the Spring, and protected from frost, will mature its bolls in the Autumn, south of 40° or 41°, and *bloom* wherever corn will grow. The plant grows 3 feet to 5 feet high; the flowers are showy—bright yellow, with purple eye. Sow at corn-planting, in drills, and thin to 18 inches apart.

No. 111.—Castor Oil Bean (*Ricinus communis*).—A stately plant, 5 to 10 feet high, with broad tropical foliage, which is showy and beautiful. It is a very rank grower, and needs a rich, warm soil. Sow in the open ground, and leave 2 to 3 feet apart.

No. 122.—Canterbury Bell. (*Campanula medza.*)—Showy, pretty biennials, flowering the second year from seed, and sometimes living 3 or 4 years. They bloom along a spike 2 to 3 feet high; flowers of perfect bell shape, large, and in some varieties double; white, lilac, blue, and intermediate shades. Sow at any time in May or June, and transplant in the Fall to 1 foot apart in rows, or set in groups.

No. 123.—Gilia (*G. nivalis.*)—An annual of 1 foot in hight, delicate growth; white or variegated flowers, growing in panicles, and finely divided leaves. Good for massing. Sow early in Spring.

No. 124.—Whitlavia (*W. grandiflora.*)—This new California annual pleases us much, blooming 5 to 6 weeks from sowing, and continuing in flower until October. Its blue, bell-shaped flowers resemble the campanulas. Sow

early in May, and thin to 6 inches apart, as it only attains a hight of 1 foot.

No. 125.—STANDING CYPRESS. (*Ipomopsis elegans*—regarded by some as a *Gilia.*) A very beautiful biennial. The foliage and habit is feathery and delicate, the flowers rich scarlet, borne on a spike 1 hight 2 to 4 feet. Sow in Spring and slightly protect in Winter; blooms all July and August.

No. 126.—LONG-TUBED CENTRANTHUS (*C. macrosiphon.*)—An annual of rather delicate appearance, but hardy and desirable. Flowers fascicled, (in bundles or clusters,) tubular, borne on stalks 10 to 12 inches high. Continues in bloom until frost. Sow early in Spring, and thin to 6 inches.

No. 127.—LARGE FLOWERING MALOPE (*Malope grandiflora*).—A fine annual of the mallows family, 2 to 3 feet high, with large rosy crimson flowers, blooming from June to October. Sow in May, one foot apart in rows.

No. 128.—SWAN RIVER DAISY (*Brachycome iberidifolia.*) —A very pretty annual of dwarf habit, growing 6 to 8 inches high, with dark blue, pink and white flowers which open from July to September. Sow early in Spring.

No. 129.—BEAUTIFUL CLARKIA (*Clarkia pulchella.*)—A hardy, Rocky Mountain annual of decided beauty, growing 1 foot high. Flowers, light purple, opening from June to September. Sow last of April or first of May. A good border flower.

No. 171. FORGET ME NOT (*Myosotis palustris*).—Low growing perennial with delicate flowers in clusters of light blue color, with white or yellow eyes. Blooms the first season. Sow in early spring. Flourishes in good, somewhat shaded, garden soils, but delights in moisture.

No. 173.—MIXED LARKSPURS (*Delphinium consolida.*) Annuals of white, rose, pink, blue, and variegated colors, growing from 2 to 3 feet high. Some of the species are double and very pretty. Flowers in spikes for a long time in succession. Sow very early, as the seeds lie long in the ground; they are very hardy.

No. 175.—MIXED SALPIGLOSSIS (*Salpiglossis atropurpurea, atrococcinea, azurea*, etc.)—Originally from Chili, where they are perennials, but with us they are annuals, sown early in frames and afterward planted in the open ground. Flowers beautiful, of various colors.

No. 177.—QUAKING GRASS (*Briza gracilis*).—A beautiful nodding grass, growing 2 feet high. The heads or panicles resemble the rattles of the rattlesnake, and dry so as to be very ornamental in bouquets of dried flowers. Sow in early Spring.

No. 182.—SWEET ALYSSUM (*Alyssum maritimum.*)—An annual, nearly 1 foot in hight, flowering in long racemes, from June to November, or until killed by frost. Sweet-scented; flowers white. Sow in early Spring, and thin to 1 foot apart, unless massed, for which it is well suited.

No. 183.—IMPROVED FRENCH AND GERMAN ASTERS.—A beautiful, hardy annual; see description and mode of culture, on page 16. Many of our own plants furnish more beautiful and perfect blooms than those there shown. Owing to the limited production of seed in perfect flowers, our parcels must be small if the demand is large, although we have saved for distribution all that ripened on a quarter acre.

No. 200.—FANCY GOURDS (*Lagenaria vulgaris, in var.*) —Cultivated for the singularity or beauty of the fruit; vines climbing. Plant like cucumbers, near a trellis, or provide poles; protect against insects.

No. 202.—ANIMATED OATS (*Avena sensitiva*).—A large oat-like grass; the seed very hairy, having long, strong, twisted and bent crosses (or beards), which revolve and twist when they become damper or dryer. They are effected by the warmth of the hand, and both look and move like insects. Sow May 1.

No. 203 and 204.—GERMAN AND FRENCH POPPIES (*Papaver somniferum and Rhœas fl. pl.*).—Of this common yet very showy species there is an infinite variety in form and color. The culture is simple. Sow in beginning of Spring, thin out to several inches apart: bloom in July.

No. 205.—DOUBLE FRENCH MARIGOLD (*Tagetes patula fl. pl.*)—A very showy annual of 2 to 3 feet high; flowers bright yellow to dark brown, and often beautifully striped and margined: of fine form. Sow beginning of May: blooms from July to frost.

No. 206.—GOLDEN STRAW-FLOWER (*Helichrysum bracteatum, etc.*)—One of the most common of the *immortelle* or everlasting flowers; flowers yellow, white, pink and scarlet. Grows 2 or 3 feet high. Sow upon borders in May. Pick flowers before expanded, for Winter bouquets.

No. 207.—SWAN RIVER IMMORTELLE. (*Rhodanthe Manglesii.*)—One of the most delicate and beautiful of annuals; a foot high, branching habit. The numerous silvery buds expand to starry, rose-colored, fadeless flowers. Sow the light seed shallow in sandy loam. It is very pretty grown in pots. Sow in May, and leave 1 foot apart.

No. 208.—GLOBE AMARANTH (*Gomphrena globosa*).—One of the fadeless flowers, regarded as emblems of immortality. It grows 1 to 2 feet high. The flowers are in globular heads, ½ to ¾ in. diameter. Sow as early as the soil is warm, and protect from frost, or better sow in the hot-bed in April and transplant to the garden in May.

No. 209.—DWARF BLUE LARKSPUR (*Delphinium formosum.*)—A fine herbaceous perennial, usually with branching stems 1½ inches high; flowers ultramarine blue, very rich; continues in bloom from July to September. Sow early in May.

No. 210.—DWARF MORNING GLORY (*Convolvulus tricolor*).—A very showy annual, growing 14 to 20 inches high; the funnel shaped flowers, blue, white and yellow. Sow early in May. Blooms from June to October.

No. 211.—FINE MIXED LUPINS (*Lupinus*).—The lupins comprise some of our most showy border flowers, and there is a great variety comprised in several botanical species. The pea-shaped flowers grow in spikes or clusters, and are of yellow, blue, white, pink, and other tints. Sow very early and thin, or transplant 6 inches or 1 foot apart. The more delicate varieties do best sown later. Middle to last of May.

No. 212.—SWEET PEAS (*Lathyrus odoratus.*)—A familiar annual, valued for the remarkable sweetness and beauty of its flowers. Its habit, mode of flowering, etc., is much like the garden pea, but it is much more delicate. The flowers are of many bright colors, (red, white and blue,) beautiful in bouquets.—A great favorite. Sow early, in good soil, seeds 2 inches apart; requires brushing; grows 2 to 6 feet high.

No 213.—IMMORTELLE (*Xeranthemum annuum.*)—An other beautiful everlasting flower. The flowers are fadeless, purple, red, white, pink, yellow, etc.; grow from 2 to 3 feet high. Sow early in Spring.

No. 214.—BALLOON VINE (*Cardiospermum haliacabum.* —A curious climbing vine, native of the river banks west of the Mississippi. The seeds are grey in a large inflated capsule. Vine 4 to 6 feet long. Sow early, in the open ground; flowers in July and August.

No. 215.—ESCHSCHOLTZIA VINE (*E. Scaber*).—A rapid growing climber, with pretty, compact foliage, from which the numerous clusters of light orange colored flowers project. Sow in place of wheel; bears a profusion till quite late. Sow in pots or frames, so as to have it blown all summer, or in the open ground, cover slightly; transplant near old stumps or trellisses.

No. 216.—ACCROCLINIUM (*A. roseum.*)—An everlasting flower, similar to but more robust and hardy than No. 207. Grows from 1 to 2 feet high; flowers rose-color, very pretty. Sow middle of May, in sandy loam, or grow in pots and turn out into the open border first of June. In stiff soil, make drills, and cover lightly with sandy soil.

Exhibition Tables at the Office of the American Agriculturist.

In addition to the Corn Bread, noticed on page 25, the following articles have been exhibited since last report:

VEGETABLES, ETC.—*Potatoes.*—Worcester's Seedling and California Seedling, exhibited by Henry Edgar, Thompson, L. I.....Sweet potatoes, by Wm. M. Taylor, Bayport, L. I.....Two hills sweet potatoes, by J. C. Thompson, Staten Island.....Another freak of nature, a sweet potato, grown through a buckle-hole. In a leather strap, by Mrs. R. H. Tanery, Bridgeport, N. J.....Garnet Chili potato, reported yield 253 bushels to the acre, by Haskell Brothers, Seneca Falls, Seneca Co., N. Y.....By H. Foster, Babylon, L. I.....Collection of potatoes, very fine, by W. S. Carpenter, Rye, N. Y.....*Beans.*—Chili beans, very large superior flavor and extraordinary size, by W. F. Heins, Esq., Woodstock, N. Y.....A New Fever and ague bean, and yard beans, by John P. Simmons, N. J.....*Cauliflower.*—Very large, by W. F. Heins, Woodstock, N. Y.....*Squashes, etc.*—Boston marrow and true hubbard squash, S. S. Conover, Washington Market, N. Y.....Hubbard squash, by I. D. McCabe, Searsdale, N. Y.....Crooked neck squash, by R. M. Cary, Factoryville, L. I.....*Tomatoes.*—Very fine and large, by Edward Walter, Fort Lee, N. Y.....Five Tomatoes, by Caleb Lyon, Georgetown, L. I.....*Onions.*—Red and white by W. J. Spence, L. I.....*Pine Apple* in full perfection, nearly ripe, in pot, by C. H. Lilienthal, Yonkers, N. Y.....Fine Apple pumpkin, by S. B. Conover, Washington Market, N. Y.....Two seven year pumpkins, one of which is now 4 years old, and the other one year old, both in beautiful preservation, kept only in a dry cellar; by J. C. Thompson, Staten Island.....Still another freak of nature, a beet grown through a keel bone, by Cummings, editor of New-York Observer, Rye, N. Y.....A carrot, very fine, 3½ lbs., by P. S. Sheperd, Mamaroneck, N. Y.....A large Lima pumpkin, of fine shape, 7 feet 2 inches in circumference and weighing, when picked, 204 lbs. by Geo. Barclay, New Hamburg, Dutchess Co., N. Y.....Long Island Beet, 15 lbs., by Charles King, Port Richmond, S. I., N. Y.....Long white French turnip, 11¼ lbs. Long orange carrot, Long Red beet, King Philip corn, fine, and parsneps, by A. M. H., Rye, N. Y. (came by express, full name not given).....Mangel wurzel, by Mr. Jones, Lyons Farms, N. J.....Turnip Beet, 14¾ lbs., by J. E. Chapman, Perth Amboy, N. J.....California bottle Gourd, 3 feet 10 inches long, by Joseph Schare, Brooklyn, N. Y.....Strap leaf turnips, and fine green-top yellow carrots, by L. Jacobs, Westfield, S. I., N. Y.....Large Radish, 3 lbs., East 76th street, N. Y.....White Sugar Beet Mr. Plato, Harlem Depot, Conn.....Onions, grown by Joseph Storres, Madison, N. J.....One root of red clover 5 feet high, S. Barfoot, Kent Co., Md.—Solid white celery, very large and fine, grown by Wm. Hennessy, Yonkers, N. Y.....Zea maize, gardener to Wm. Shaw, Esq., Clifton, S. I., N. Y.....Crystal flint corn, and 8 rowed thin flint, by D. W. Brower, Bergen Co., N. J.....First importation of cotton from *Beaufort, S. C.*, by Henry J. Winser, Esq., (of N. Y. Times).....16 and 8 rowed corn, L. Cubington, Compass Douglass Co., Ill.....Jersey white and yellow corn, very fine, by J. Wood, Rockaway, N. J.....Java wheat, China Tea wheat, and mammoth timothy heads, by Mr. Hicksinson, St. Johnsville, Vt.....Cotton grown out of doors, and by Orange Judd, Flushing, L. I.....Full of the Orange, by Mr. Brick, Brooklyn, L. I.....Japanese Quince, by Mr. Wyatt, Manassas, Staten Island.....A variety of Apples, by Miss Knowles, Middletown, Conn.....Baker Apples, fine, by F. A. Rockwell, Ridgefield, Conn.....Sample of Apples, grown from Isabella, flowered in 2nd week of August, 16 bunches on vine 14 years old, remarkable, by Wm. Cone, South-8th Street, Brooklyn, E. D.....Joan Apples, by G. Welsher, Staten Island.....Grapes wanting a name, by P. W. Caesar, 20 Beaver-st., New-York.....Catawba Grapes, G. Pendell, Hempstead, N. Y.....Seedling Apples, wanting a name, from D. C. Beuton, Quincy, Ill.....Pecan Nuts, and bottom Hickory Nuts, by J. Wesley Woodruff, Quincy, Ill.

FLOWERS.—Apple blossom (several on the tree, Oct. 19th), by Mr. Hume, Manhattanville, N. Y.....Cut flowers in profusion of various kinds, also red and yellow Capsicums, by O. Judd, Flushing, N. Y.....Pompone Chrysanthemums, Dahlias, Cut flowers, (at various times) Carnations, etc., by C. S. Pell, N. Y. Orphan Asylum.....Dahlias and Monthly Belgian Honeysuckle, by John F. Simmons, N. J.....Abutilons, Cobaea, Zinnias, roses, etc., by C. S. Pell, Orphan Asylum.....Pompone Chrysanthemums, very fine, from Peter Henderson, Jersey-City, N. J. and John Mc. N. Y.....Chrysanthemums, most tastefully arranged on card board upon white paper, 64 varieties, some the newest, by W. F. Heins, Esq., Woodstock, N. Y.....Dahlias, very fine blooms, by C. Lilienthal, Yonkers, N. Y.....Splendid Bouquet, of many hundreds of bloom, gathered Nov. 19th, and made up of dwarf and pompone Chrysanthemums, Agrostemma Principalis, Stocks, evergreens, etc., etc., by W. F. Heins, Woodstock, N. Y.....Winter Cherry, Physalis Francheti, fine, by Jacob Youngs, Greenport, L. I.....Two Yuccas, Seedling, by A. S. Fuller, Brooklyn.

MISCELLANEOUS.—Horned Toad, from A. S. Siler, Santa Fe Co., Utah Territory.....Hive Bee, by C. E. Miller, N. Y.....Tomato Wine, made in 1859, by W. F. Heins, Woodstock, N. Y.....Sewing cotton, by Wm. Thompson, Staten Island.....New Fruit Picker, by A. M. Halsted, Rye, N. Y., and another by N. G. Carnes, Riverdale, L. I.....A piece of flag worn from the Weehawken Frigate during the bombardment of Port Royal, by J. McCarthy. Honey, fine specimen of clover make, in glass case, by M. Quinby, Coeymansville, N. Y.

☞ Our tables are always free for the exhibition of useful articles, or those interesting to the public. Those pertaining to the Farm, Garden, or Household, are most appropriate.

Cotton in the Central States.

Not the perennial cotton which has made some talk of late, and which has been selling at 20 cents per seed, but the common cotton of the Southern States. We have now, well ripened samples of cotton bolls, fibres, grown in open ground, in Westchester County, N. Y., and others have been shown from Long Island and New-Jersey, raised last year. This establishes the fact that, in favorable seasons, good cotton can be raised so far north as 41°, and that it will ripen in any ordinary season in Delaware, Maryland, Southern Ohio, Indiana, Illinois, Missouri, Kansas, and California. It will doubtless be planted more or less in all of these States, and further north by starting seeds in hot-beds, and afterward planting out in the open ground. There is no difficulty in the treatment. The seed vegetates readily, and if sown where it is to grow, may be 3 or 4 feet apart, drilled in thickly, and afterwards thinned to 15 or 18 inches distant. A seed drill will greatly facilitate the planting. If started by artificial heat, prepare the hot-bed and sow about the middle of April, transplanting after all danger of frost is over, during the latter part of May.—Of course we do not expect to go into extensive cotton growing at the North, but every one may raise a little as an ornament and thus perhaps do something toward acclimating the plant

Cotton at the North.—Theo. Tilton, of New-York Independent, has raised sufficient cotton in his yard at Brooklyn, to make a shirt for himself. The seeds were started in a hot-bed, and afterward planted in the open garden, where the bolls ripened their seed. We have some of the cotton on our exhibition table.

Containing a great variety of items, including many good hints and suggestions which we give in small type and condensed form for want of space elsewhere.

To Correspondents.—Our Basket Columns are rather crowded by the necessary Seed Notes, and several items are left over. Indeed, we are now receiving a great number of hints, queries, etc., in renewal letters, which will furnish interesting topics to be discussed as we have room hereafter. We solicit such items without limit.

The Prize Essays.—In response to our offers, some sixty essays were sent in. They have been handed over to competent committees, who are at work upon them as they have time; but as there are more than **1500** pages of manuscript to be read over, it will require considerable time to go through with the whole, and decide upon their relative merits. As fast as we receive the decisions in the several classes, the successful competitors will be notified and the money be subject to their order. We shall publish the best essays in the order most appropriate to the successive seasons.

A Young Man who knows nothing of Farming.—J. V. will do well to put his $300 at interest, and to hire himself to a good farmer, till his $300 becomes $400, and he becomes pretty well initiated into the business. We would about as soon undertake to live by our pen without knowing our letters, as to live by farming without some previous experience,—such as he could get with a first-rate farmer.

A Great Pumpkin.—We have had "some pumpkins" on exhibition since the harvest season, the largest of which is a Lima variety which was raised by Mr. Geo. Barclay of Dutchess Co., N. Y., and weighed 304 pounds, when taken from the field. It is of an orange color, splashed with cream, oblately flattened, and ribbed. It measures 7 feet 2 inches in circumference.

A Chestnut Orchard.—The Chardon Democrat says that E. J. Ferriss, of Lake Co., O., has an orchard of 100 chestnut trees, just coming into bearing. He has an accidental variety, very large and early, which he is multiplying by engrafting, and is sanguine that chestnut culture will prove remunerative, as late frosts in the Spring never injure the flowers, as they do not appear until about the 10th of July.

Iowa Apples.—Mr. A. S. Fuller placed on our Exhibition tables, Dec. 16, samples of Fall Pippins, Northern Spy, Mountain Pippin, White Winter Pearmain, Peck's Pleasant, Swaar, Melon, McClellan, Winter Sweet, Belmont, Raules Jannet, Ladies Sweeting, Pryors Red, Rambo, Newtown Spitzenberg, Black Gilliflower, and Hays Winter Wine. They were fine specimens raised by Mr. Henry Avery of Burlington, Iowa, and compare very favorably with the same varieties grown at the East.

Buried Apples.—"Experimentor," writing from Wyoming Co., Pa., says: I have tried several plans for preserving apples but have never found any thing that pleases me better than the old fashioned Dutchess County way. Take perfectly sound apples, and bury them in a dry place in the garden and keep them dry. Put 5 to 10 bushels in a heap; cover with about 3 or 4 inches of straw, and then with about the same depth of earth, leaving a small hole at the top, and then cover the whole with a straw cap. Or better with a roof of boards or slabs. Apples treated in this manner retain their flavor, which is of the greatest importance. I have often, for sale fall and early winter use, packed them in sawdust, wheat and oats chaff or wheat bran, dry sand, and in wooden buckets, etc., but none of these experiments have pleased me. They will not rot, but loose their fruity flavor.

White Doyenne Pear.—(E. Blosser, Middlesex Co., Conn.) This is the old Virgalieu, which, though generally discarded in New-England, is still a fine pear at the West. As a dwarf, it succeeds pretty well hereabouts.

Mixing Grapes.—Enquirer may plant as many kinds as he pleases on the same trellis. The intermixture of the pollen will not affect perceptibly the perfection, or flavor of the fruit. A very strong growing variety and gross feeder will so take the nourishment out of the soil, that thus its delicate neighbor will be nearly starved. The Concord will rob a Delaware if planted too close, and care is not taken to prevent the robbery.

Old Huckleberry Pastures as Vineyard Sites.—(J. C., Jr.)—The subject is too extensive for a Basket article. If the exposure is southeast or south, and the ground dry and not too leachy, and if you have plenty of manure and can apply 100 or 150 dollars' worth per acre, composted with twice its bulk of muck, and expend an equal sum in labor, your 2 or 3 acres of huckleberry pasture will make a good vineyard. Your selection of grapes is probably good; the Delaware should have a prominent place.

Aromatic Plants.—Trees of the Myrtle and Laurel families abound in China, Japan and Australia. These families of plants produce cloves, cajeput oil, gum kino, etc. (from myrtaceous plants), camphor, cinnamon, cassia, benzoin, sassafras, etc., (from the Laurineous plants). The Revue Horticole states that the atmosphere of Australia is so filled with the odors from these trees that fevers never exist, even in apparently the most malarious of swamps.

How Large a Garden.—"Ex City Subscriber" inquires "How much land will be needed for a kitchen garden for a family of five persons, with a liberal shiftwance for City cousins. For raising Garden Sauce vegetables and small fruits a quarter of an acre would be ample. Half an acre could be profitably used in providing a supply of extra vegetables, with potatoes, etc., for Winter use.

Second Crop of Radishes.—The first week in Dec., George Haywood, of Brooklyn, placed upon our table crisp and tender radishes, from seed grown the same season. The first crop was sown early in May, and a few left to ripen seed, and this in turn was sown the last of September. They have been in eating condition for some weeks, and were of the scarlet turnip-shaped variety.

Old Asparagus Beds.—("Old Will.") Use plenty of manure in the Fall either as a top dressing or forked in, and salt well in the Spring.

Rhododendron—Correction.—In the article page 368, Dec. No., on transplanting the Rhododendron, by Mr. L. H. Johns, the color should have been printed *blush* white, instead of blueish white.

Raspberry Jam and Wine.—The Western Railroad Gazette states, that 12 to 15 tuns of raspberry jam, and from 300 to 400 gallons raspberry wine are annually made on Sugar Island, in the Sault St. Marie River, Mich. The berries are gathered by the Indians and sold to parties who manufacture the jam and wine, and send it to Chicago and other cities for a market.

Red Clover.—Branch 5 feet long received from S. Barfoot, Kent Co., C. W., a large growth but not equal to that referred to on page 329, last volume.

Rhyme—Poetry.—We are often favored with contributions of rhyme, and occasional bits of real poetry; but we can publish very little, if any, of such material. If there were no other objection, this one is fatal, viz.: the difficulty of properly translating English poetry into German, and *vice versa*—and since all articles go into each edition, we are obliged to omit poetry, as a general rule.

Snow Cream.—Mrs. M. A. H. Rowe, Columbia Co., N. Y., says the following is quite equal to ice cream. Beat thoroughly 1 egg with 1 cup white sugar, add 1 cup sweet cream, flavor to the taste, and stir in snow until it is quite stiff.

Beef and Pork Pickle—Correction.—The recipe at the foot of page 357 of our last issue was singularly misprinted. Mr. Aten who sent us the recipe pointed out the mistake. It should read—4 gallons water, 3 quarts salt, 1 pint molasses, 2 oz. saltpetre.

Recipe Wanted.—J. Henderson, Mifflin Co., Pa., inquires for directions for making the French national dish called "Pot-a-feu."

The Last First.—On the *last* page of the November number of one of our competitors for public favor and patronage we read: "The rapidly increasing circulation of this journal . . and its daily increasing popularity proves it to have become an established fact."—— On the *first* page we read: "The publication of this paper will necessarily be discontinued with the next number. . . ." Evidently the last written item is placed first.

A Valuable Opinion.—A recent *Maine Farmer*, (a journal devoted to news and agriculture,) says: "Those of our readers who want a *practical* and *reliable* monthly Agricultural Journal, issued in good form for binding, and containing numerous illustrations, we would advise to subscribe for the *American Agriculturist*. . . ." This, coming as it does from one engaged in the same line of business, we consider as the highest praise. It also exhibits just the feeling we like to see and strive to cherish, which is above petty jealousy. The Maine Farmer, edited by Dr. Holmes, and published by Messrs. Homan & Badger, at Augusta, Me., ($2 on a year,) is always one of our welcome exchanges.

"Manual of Agriculture, for the School, the Farm, and the Fireside." This book of 306 pages, prepared by Messrs. Geo. B. Emerson and Chas. L. Flint, and published by Messrs. Swan, Brewer & Tileston, (75c.) we have had on our table for several weeks, dipping into it now and then, and uncertain whether to give it a strong endorsement or not. It is one of the most thoroughly edited agricultural works published, and this will be the main obstacle to its general introduction. It is close reading—many thoughts packed in few words—and, while well adapted to older minds, will be rather strong mental food for children. A good teacher, experienced in agriculture, using this as a book of topics, would make it interesting. The fact is that which may be useful in stating unquestioned truths; we should have preferred more of illustrative argument. While approving of the doctrines of the book as a whole, there are some statements which we should call in question, had we time and room for an extended review.

Book on Breeding of Domestic Animals.—A valuable little work of 164 pages, by S. L. Goodale, Secretary of Maine Agricultural Society, in which is discussed the principles of breeding, or the physical laws involved in the reproduction and improvement of domestic animals. Correct knowledge on this subject is important as well as interesting to every one, and Mr. Goodale has furnished much valuable information, and many useful facts and hints, condensed and systematically arranged. (Price, 50 cents, postpaid.)

Two Rules for the Barn.—1. Feed regularly. All animals desire their food at stated intervals, and digest it better when fed at about the same hour daily. 2. Feed uniformly and moderately. Do not give an excess one day, and too little another day. Let the fodder be proportioned in kind and amount to the animal; then let it be given systematically.—*Old Reader.*

Transferring Wild Bees.—"Bee Hunter," Providence, R. I., and others can either cut down the "bee-tree" and saw off the section containing the honey and set it near the stand; or they can place a common hive or box over an orifice made in one end of the section, and hive smoke into the other end to drive the bees from the combs. Then cut into the log and carefully remove the comb in as large pieces as possible, and fit them into the movable frames, or box of another hive, securing them with the help of cross sticks. Put in about 25 lbs. honey and brood comb for Winter use, and drive the bees into the hive, where they will make a contented home.

Destroying Moles.—Mr. Geo. Barclay of Dutchess Co., N. Y., puts sheets of tin across the new made mole tracks running them in so slanting as to throw the moles upon the surface in their attempt to work past them. Once on the surface they are easily killed by cats, terriers or boys. Two pieces of tin should be placed in each run, the upper edges approximating, as it is not known from which direction the animal will come.

James Warden, Baltimore Co., Md., kills moles by sinking glazed earthen pots beneath their runs. They cannot get out when once in. Post holes dug with a spade or bored with a post-hole auger is said to answer the same end.

Rusty Straw Unfit for Feeding.—R. McClure, in the Farmer and Gardener, gives an account of the injurious effects of rusty straw fed to horses, causing almost immediate sickness and death to a large number of animals belonging to a cavalry regiment. A decoction made from rusty straw given as an experiment caused loss of appetite, and sickness.

How to keep a Cow on Cape Cod.—(R. C., Jr.)—Pressed or "bundle" hay will probably cost you 1 cent per pound. A ton of hay ($30,) a ton of straw ($8,) and a ton of cornstalks ($5;) with what meal and roots she ought to eat, will keep your cow a year. In the Winter, give her cut feed,—half hay, with straw and stalks, wet up with 3 quarts corn meal (or 4 quarts **ship-**

stuff, or 2 quarts oil meal); of this about 1 bushel morning and evening, and ½ bushel of sugar beets or mangel-wurzels cut fine. This feed will cost 23 to 30 cents a day. In the Summer, give her pasturage, if you can, and feed her nice "slops" or swill, with dry hay, every night. Her manure will enable you to raise green feed (corn, etc.) for her the second year, and thus, each year she will cost you less. She should give you, on an average, 8 to 10 quarts of milk a day, the year round, worth 32 to 50 cents a day.—This is *one* way to do it. If this does not suit your circumstances, we may try again.

The effect of Cold on fattening Animals.—Dr. Playfair, in the Journal of the Royal Agricultural Society, in speaking of the necessity of warmth to fatten an animal readily, says that to keep up the animal heat, the oxygen of the air unites with that portion of the blood which goes to form fat and tissues, and converts it into carbonic acid, water, and animals. Where all the vitality of the animal is used to manufacture heat, there is no power left to increase the fat. If we would fatten animals in winter we must give them a summer temperature, by warming the shed and stables they occupy. The air that they breathe should be as pure as possible.

Another Prolific Sow.—Wm. P. Hood, Bristol Co., Mass., claims to have the most prolific sow yet noticed in the *Agriculturist*—a Berkshire sow, 2 years and 7 months old, that has given birth to 87 pigs in five litters. The largest litter contained 19, the smallest, 16 pigs. He says she transmits her prolificness to her offspring.

Kidney Worms in Hogs.—H. J. Hulling, La Salle Co., Ill. In addition to the remedies given on page 220, (August No.) of last volume, administer spirits of turpentine in moderate doses, which, though harmless to the animal, is very destructive to worms. The disease often proves fatal, and prevention is much better than attempted cure.

The Army Worm.—Henry Griffing, Jasper Co., Ill., writes to the *American Agriculturist* that he doubts the correctness of Dr. Fitch's theory that the army worm originates in swamps, as published on page 331, Vol. XIX. He says it was very destructive in his neighborhood, and there are no swamps for several counties around. In that section the worms originated wholly in Timothy grass meadows.

Ventilation of Barns.—Unfortunately there are yet in our country few barns that need airing. Most are aired altogether too much for the comfort and thrift of the animals. But some barns are tightly built, the foundation of mason work, or thoroughly banked, the floors mostly air tight, and the sides closely boarded, or battened. In these provision for ventilation should be made. A ventilator, in the central part of the ridge, in the form of a small tower, is both ornamental and useful. Especially give horses pure air. They should never pass the night in an atmosphere polluted with exhalations arising from other animals. It is not only unpleasant to them, but detracts from their power to labor.

Ventilation of Stables.—"Iowa subscriber." Run a trunk of matched boards 3½ or 4 feet square up from somewhere near the middle over the cattle floor, passing one side of the threshing floor to the roof. It need not pass out, but must come close to a self-ventilator like the one figured on page 12. It is of course flush with the ceiling of the cattle floor. Swinging doors at one or two places in it are exceedingly convenient for throwing down hay, cut-feed, or straw, from the floor or loft above. These doors should swing from the tops so as always to remain shut when not in use. You will find such a ventilator sufficient, convenient, and cheap.

Condition Powders.—(J. D. Belcher.)—There are many kinds, good enough, perhaps; but the following we *know* to be good: Mix one part of salt with five parts of wood ashes, and stir it into the mess fed to your stock. We can not specify just how often, but give it whenever an animal seems to need it. This will sharpen the appetite, and keep stock in good, healthy condition. It will generally obviate the necessity of using any other medicine. The condition powders of the "horse-doctors" have usually antimony for their basis—often also contain *arsenic*, and other drugs, which it is never best to give, except for some real cause. Ginger, aniseseed, and other spicy or aromatic articles, are common ingredients to disguise the taste, and may be used for their tonic effect, often with profit, and without danger. *

"Dead Ground."—Henry C. McCoy, of Somerset Co., Md., writes: "I live in a sweet potato country, and our land often becomes "*dead*" in places of 20 feet square, but only when sweet potatoes are grown. The same spot will bring corn or almost any other kind of produce". . The remedy is, of course, a removal of the cause, which, as we do not comprehend, we can only say in general, secure a free circulation of air and freedom from water in the soil by draining thoroughly; see if you can find any external or other difference in the character of the soil. Try an application of freshly-slacked lime at the rate of half a bushel to such a spot as you mention. "

How Much Manure for Wheat?—The impression prevails in many quarters at the east, that the reason why we do not raise our own wheat is because it requires so much manure. "Triticum" inquires, Is it true that two-horse cart-loads of stall manure are required to raise 25 bushels of wheat per acre? Wheat does not require more manure than Indian corn, but it does require a superior mechanical preparation of the soil. Those of our readers who systematically manure for wheat in whatever way will favor "Triticum," and doubtless many others by communicating their modes of culture for our columns. Of course, no rule can be given applicable to all soils. The idea is, we suppose, to ascertain how much of a given kind of manure will *pay* on a particular kind of soil.

Keeping Potatoes.—John C. Bishop, of Fond du Lac County, Wis., for some years has followed with great success the plan which he describes as follows: "They are dug about the middle of October, when the ground is dry. All the fine dirt falling into the bottom of the wagon is put in with the potatoes; as they sweat, the dry dirt absorbs the moisture. The bins are about two feet wide, raised from the cellar bottom six or eight inches. Their sides are set out from the wall by a 2x4 inch stick, and so between the bins. This prevents any external dampness from coming in contact with the potatoes; the air circulates around them, and I am convinced that potatoes so kept will be sounder and freer from disease than in any other way. A bin 14 feet long by 2 feet wide and 6 feet high, will hold over a hundred bushels. Such a bin will contain 220 feet of lumber."

How to Keep Winter Squashes.—

"Agin the chimbly crooknecks hung,
And in the corner 'ou roasted
The old queen's-arm, that grandsir Young
Fetched hum from Concord, busted."

So runs the Yankee ballad of Zekel's courtship. Our frugal ancestry understood better than we, perhaps, how necessary a warm, dry place was to keep winter squashes. We may pattern from them and keep our Hubbards, crooknecks, and marrows out of damp cellars or freezing lofts.

Varnishing Cheeses.—A writer in the Dairy Farmer states that it is the practice of some dairymen to coat each cheese thinly with a varnish made from gum shellac dissolved in alcohol, when about to be shipped for market. It is said to improve the appearance of the cheese and to keep it from losing weight and gathering mold. We can not say as to the value of this recommendation.

To Keep Cranberries Fresh.—J. R. First see that *all* are sound and plump, then put them in tubs or large jars, fill the same with water, and keep in a cold cellar, without freezing.

Use of the Plow in Draining.—A writer in the N. H. Journal of Agriculture does most of the labor of ditching with a plow. He plows two furrows and throws out the earth. This is sufficiently wide for the drain. Two more furrows are in like manner plowed, and the earth thrown out by hand, when the plow is chained to the centre of a long, strong pole, laid across the drain, and two pair of oxen hitched on—one yoke on each side of the ditch. As the ditch grows deeper, the chain is lengthened, until 4 to 6 feet in depth is reached. This is very similar to the method described and illustrated in the *Agriculturist* for last October, page 297.

Board Drains.—D. M. Allen, of Cuyahoga Co., O., uses inch boards nailed together "like an eaves-trough," and laid open side down, for under-drains, and wishes to know if any of our readers have had experience with such drains, and can inform him in regard to their effectiveness, durability, etc.

Gas Lime.—We must refer inquirers to the number of the *Agriculturist* for March, 1861, (page 75, last volume,) for full information on this subject. It will generally pay to cart it several miles, but before it is used it must be thoroughly spread out to air, be broken up fine, and composted with muck or earth. Such a compost ought to lie six months before it is used; and after it is incorporated with the soil, two or three weeks should elapse before sowing grain or grass seed. We would not advise R. W. to apply it to his pear trees without trying an experiment or two, and watching the result.

Musical Instruction.—L. Winfield, Orange Co., N. Y., suggests that an elementary course of musical instruction be given in the Boys' and Girls' Department of the *Agriculturist*. It would not do to encroach upon the crowded space given to the children, with matter which can be as easily obtained in books; besides, we have little faith in musical instruction unaccompanied by the living teacher.

Ladies' Feet.—"Died of thin shoes"; so runs the epitaph. Thank Providence it is the fashion both for ladies and gentlemen now, to wear thick and sensible ones. So arguments against thin shoes are waste breath—and we can only say, follow the fashion.

Ventilation of Sleeping Rooms.—A correspondent of the *Agriculturist* writes: Sleeping rooms, in which there has been a fire during the day, should be aired before retiring. The importance of sleeping in a fine, bracing atmosphere can hardly be overstated. Even if there has been no fire during the day, it is well to open a door and a window or two, and to fill the room with entirely fresh atmosphere. Persons who will try this, need not take our word for the benefit. They will realize it in the greater elasticity and freshness with which they will arise in the morning.

Transferring Prints upon Wood, etc.—(C. C. R.)—This is done, we believe, by coating the surface with copal varnish, and before it is dry laying on the picture (wood-cuts transfer best) and smoothing it down upon the varnish with a paper folder. When the varnish is dry, moisten the paper and rub it off with the finger, and after carefully removing the paper, the print will be left; then give it another coat or two of varnish.

Lightning Rods.—(I. S.) Put up a ¾-inch iron rod, screw-jointed, running up one end of the barn, along the ridge-pole, having a single-pointed silver-tipped rod two or three feet high, at each end of the ridge-pole, and one extending equally high above the ventilator in the middle of the roof; have the end carried well down into earth which remains moist the year round.

Effect of Electrical Light on Vegetation.—Plants bleached by the exclusion of light, will grow green if exposed to the action of *electrical light* for a few days, in the same way as if acted upon by the solar rays. This is learned by recent experiments made in France, and noticed in the *Comptus Rendus*. It shows that even in these most delicate chemical effects, the light from the two sources is identical.

Do Rats Eat Grapes?—This inquiry recently mooted in the Gardener's Chronicle, (Eng.,) elicited many facts showing that these vermin do climb walls, trellises, and vines in houses to devour the fruit, in some cases taking it to their holes, where it was found.

A Hint to Stove Makers.—A writer in the Rural New-Yorker asks that stove manufacturers would leave off all the beading and figures and flowers and "ifficks" from their patterns. It would save much expense, and make it much less troublesome for housekeepers to black and polish the stoves. Some ornament may be allowed on parlor stoves, but nothing more than a simple plating to increase the heating surface should be used on a cooking stove.

Well Apparatus.—"Ex City Subscriber." The self dipping and dumping apparatus for raising water from wells, if rightly made, is superior to the old fashioned drum, or the wheel and two buckets.

Coal Oil for Moles.—"J. M. K." writes to the *American Agriculturist*, that he banished the moles which were very destructive in his grounds, by the use of coal oil. A small opening was made with the finger, at intervals along their track, from a tablespoonful to a gill of the liquid was poured in, and then covered to keep in the scent. This was repeated as often as a fresh track was made, and they soon left in disgust. He recommends the crude, unrefined oil, which can be had cheaply.

Coal Oil in War.—A correspondent of the Scientific American proposes that small steamers be fitted up with tanks of coal oil so arranged as to be thrown upon vessels with a steam pump. Then by setting fire to the stream the attacked vessel could be deluged with flame. This is a bright idea *if* it can be carried into practice. Camphene or spirits of turpentine would be preferable. fire will not readily follow a stream of common coal oil.

The War Rumors.

We are happy to assure our readers that, at this date (Oct. 20), there does not appear to be any serious ground for fearing a war with England. Most of the excitement thus far has been mainly due to those unscrupulous newspapers, here and abroad, which feed and fatten upon popular commotions. To these a battle, a catastrophe, a disaster, is food and sustenance. If any wrong has been done, it will doubtless be settled by diplomatic correspondence, and not by a resort to arms. There are too many ties of interest binding this country and England together, to permit their being easily sundered. The foreign need of our surplus breadstuffs would alone be a strong incentive to the maintenance of peaceful relations, and in this respect our farmers stand as arbitrators. We firmly believe that the good prospects, which we have for months past placed before our readers, are yet to continue, and that by another month we shall be able to report the entire subsidence of the recent commotions, which have been mainly produced by the sensation Press.

Years of Scarcity and Abundance.

The uncertainty of the weather and of the crops is an old subject, but it is one about which no agriculturist can feel indifferent. Changeable as the seasons are, there is yet reason to believe that, amid much apparent uncertainty, law and order do still prevail. At least, this much may be held, that in the long run, sunshine will succeed storm, and abundance follow scarcity. There may be a year or two of poor crops, but these will soon be balanced by as many of good crops. We cannot tell how large a period the cycle may embrace, but we may be confident that a cycle there will be.

The French are more given to observing and theorizing on these subjects, than we busy Yankees are. Some time ago, M. Becquerel read a paper before the Academy of Sciences, in Paris, on the culture of wheat in France, in which he presented some statistics worth looking at. His facts show that "there is a periodicity in the recurrence of good and bad harvests; that five and six years of abundance and five or six years of scarcity follow each other pretty regularly." He quotes from Count Hugo the following table, extending 33 years:

From the year 1816 to 1821 was a period of scarcity.
From the year 1822 to 1837 was a period of abundance.
From the year 1838 to 1842 was a period of scarcity.
From the year 1833 to 1837 was a period of abundance.
From the year 1838 to 1842 was a mixed period.
From the year 1843 to 1847 was a period of scarcity.
From the year 1848 to 1852 was a period of abundance.

Now, let these facts be taken for what they are worth. They do seem to indicate a certain order and regularity amid apparent disorder. Perhaps, if we should make careful observations, we should find a similar law prevailing here. The cycle may extend three years, or five, or some other period, but undoubtedly there is some regular balancing of the seasons.

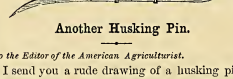
An ingenious Scotch writer thinks he has found a natural cause to explain this law. He refers to Schwabe, a German astronomer, who proves that the spots on the sun maintain a certain periodicity of about five and six years; then to Gautier, a Swiss savan, who affirms that this periodicity tallies with that of the grain crops. And he reasons that, as the light and heat of the sun are essential to the successful growth of vegetation, it is not unscientific to suppose that the diminution of them should diminish the crops, and their increase augment them.

We are not prepared as yet, to give much weight to this theory; but it will do no harm if farmers remember it as a matter for observation.

The Millers Not Always at Fault.

A correspondent, who is a miller by trade, sends to the *American Agriculturist* a somewhat lengthy communication, from which we condense the following suggestions: The mechanical skill of the miller is often called in question by housewives, when the bread does not look inviting, and his honesty in the matter of taking toll is also sometimes doubted by the farmer, when he is not at fault. Frequently, wheat which has been poorly screened from the chess, "cockle," and other foul stuff, is taken to be ground; then, if the miller grinds it just as received, without re-screening, a poor article of flour is turned out. If, however, from a desire to maintain his reputation for making good flour, he takes pains to remove the foul stuff, then the flour from the grist falls short in weight, and he is suspected of cheating in the toll. Much grain is injured by being sprouted, and in some sections it is threshed on the ground, and thus mixed with gravel or dirt, which must injure the quality of the flour. If good grain, properly screened, be taken to mill, our correspondent thinks less fault will be found with the miller, and this is undoubtedly true.

Another difficulty stated to be in the way of the miller, is the practice of having corn ground together with the cob, particularly where all the runs of stones are driven by a single water wheel. The corn, being heavier, will nearly all pass between the stones first, and when the cobs, which are more easily ground, begin to run, the mill starts off in double quick time. To remedy this, the miller gives a little more feed to the stone, and unless constantly watched, which is often impracticable, the stone is crowded, and the mill runs slowly again: thus an unsteady motion is given, and good flour can not be made on the other stones which are affected by this continued change. One remedy for this latter difficulty would be, to grind such feed only on certain days, and then have no other grain passing through the stones at the same time.



Another Husking Pin.

To the Editor of the American Agriculturist.

I send you a rude drawing of a husking pin which I have used these twelve years, and think it superior to the wooden ones of which you made a notice. It is of ¾-inch iron, made to fit the hand, the ring going round the little finger, and the point bearing against the thumb. A strap of leather, an inch wide, through the ends of which the pin passes, goes over the two middle fingers. Any common blacksmith can make the implement. ELI C. JONES.

Blair Co., Pa.

Agricultural Dentistry.

A subscriber writes to the *Agriculturist:* I like the ideas of a correspondent of the Dairy Farmer, who suggests that one operation be made of taking out the tree, body, roots, and all. For this purpose he recommends to use a stout rope eighty or more feet long, with a pully; the rope to be fastened near the top of the tree, the pulley anchored to an adjoining stump, or to a loaded stone boat, and horse or ox power applied. Small trees could thus be *extracted* at once; for large ones it would be necessary to cut some of the main roots near the surface. The tree itself would act as a lever to raise its own roots from the ground. In localities where wood is valuable, the saving of fuel in the stumps and roots brought up, would form quite an item, besides the additional land cleared at once. ROOT.

[The above we find in type, but do not attach great importance to the suggestion, from the fact that it would be found difficult to fasten the rope far enough up the trunk to obtain a sufficient leverage to pull over a tree with its green roots firmly imbedded in a strong soil. The use of a long light ladder might be found practicable. Indeed, we have seen a few trees thus removed, but they were those which had been girdled for two or three years, and most of the roots were partially decayed. In clearing oak land at the West, a somewhat common practice has been to clear out the under-brush and small trees, then girdle the larger ones, and sow a crop of wheat, following with corn. After two or three years a heavy Autumn wind blows over most of the trees, and they are cut or burned into short pieces, and logged up and burned. If any one has been successful in pulling over *green* trees with ropes, we shall be glad to hear from him in the *Agriculturist*.—O. J.]

For the American Agriculturist.

Work Bulls in the Yoke.

Idlers are dangerous members of society, and bulls are no exception. Their vicious propensities when left unemployed, make them the most dreaded animals on the farm. But however gentle they may remain, it is no small tax to support these gentlemen of leisure among farm stock. Why should they not be taught to bear the yoke and divide the labor with their less favored brethren? They have probably been left generally unused for such purposes, because of the supposed difficulty of managing them; but a well-broken, well-worked bull is a different character from the pampered sultan left to his own way. If taken young, and properly treated, they need be little more difficult to manage than oxen. The writer knew a whimsical Doctor in this State, who trained a two-year old bull to draw his sulky, and he attracted great attention, galloping about the country with this singular "turn-out." The Boston Cultivator gives the case of an imported Ayrshire bull, owned by Mr. E. R. Andrews, of West Roxbury, Mass., which is broken to single harness, and worked daily before a cart. He can pull more than any horse upon the farm. He is very tractable, easily managed, and quick in his action, walking faster than the common gait of a horse. He is guided with reins attached to a ring in his nose. If judiciously kept, and not over-worked at the time of special service, such treatment will be rather a benefit than an injury, giving greater vigor and hardiness of constitution. Let these sinecurists pay their way.

REMARKS.—The above is perhaps partly true, but we can hardly endorse the advice to put valuable breeding animals to hard work in the yoke—certainly not to work them sufficiently to make them entirely docile. Doubtless, bulls can be kept somewhat gentle by constant handling from "infancy," but to work them enough to prevent the necessity of using a ring or headrope would lessen their breeding qualities.—ED.]

"The Straw-yard."

A fine frosty morning in Merry England at Christmas time. The first considerable fall of snow lies lightly on the thatch, the wind has not drifted it, the sun has not softened it, and even in the straw-yard it is as yet unsoiled and beautiful. The haze, which gave such a depth and softness to the atmosphere before the storm has gone, and the sharp, clear outlines of distant objects tell us, even if we look out from the window, turning our backs upon the blazing and crackling hearth, of the exhilarating tonic of the purified air. The horses fill their capacious lungs with joy, and are as ready for a ten-mile drive as for a caper on the meadow, or even a pull at the hay-rack. Let us enjoy the scene with Mr. Herring, one of the most famous of the animal painters of England, whose horses on canvass bring prices which many a farmer would rejoice to get for his four-year-olds. Every animated thing is out and enjoying it too. Black Prince, a fine noble fellow, looks monarch of all he surveys; the dapple pony rejoices in the realization that on Christmas-day morning he is not, as usual, bounding away over the moor to the market. So we may give them each a character, and cogitations appropriate to their looks and circumstances. The experience of the feathery snow is evidently a new sensation to the saucy little Berkshires under Sir Roger's heels. Bold Chanticleer, ready to dispute with any claimant the right to rule the yard as well as the roost, struts and cackles with an offended dignity, as if it had all been done without his counsel or consent. Well, Mr. Herring, we are much obliged for the picture, and hope the readers of the *Agriculturist* will enjoy it as much as we.

THE STRAW-YARD AT CHRISTMAS—From a Sketch by Herring.
(Engraved for the American Agriculturist.)

Fowl Management.

At this season, poultry need looking after, if we would keep them healthy, and in good laying condition. If they are confined, the hen-house should be light, warm, airy and dry. Any thing but wet quarters for hens; and the more sunshine the better. Keep their apartments clean. Be regular in the times of feeding. Variety in diet should also be sought after. Corn is always acceptable, and so are barley, refuse wheat, oats, boiled potatoes, and the like. An occasional picking of *fresh* meat is needed for laying hens; it is a partial substitute for the worms and insects which they get in the Summer. Keep clear of salt meat, however; this is often hurtful, and sometimes fatal. Give them plenty of gravel, old plaster, or broken oyster shells, or pounded bones, and supply fresh water to them regularly.

Whoever has an eye to the improvement of his flock by breeding, should now take the matter in hand; a single year will accomplish a great deal. Examine the fowls from day to day, while they are feeding, and having fixed upon the best roosters and the best hens, put the others in the pot, as fast as wanted. Select the hens for their healthy, vigorous constitutions, large, well-formed bodies, bright eyes, and good combs. "Early maturity," says a savan in hendom, "and good laying qualities must not be forgotten. The form is a good indication of the former, and also, to a certain extent, of the latter. If early maturity, beauty of form and refinement are carried too far, the tendency to lay eggs is supposed to be diminished." Decapitate restless, quarrelsome hens. Roosters should be chosen for their vigor, upright and valiant bearing, plump and strong bodies and legs. The relative importance of the color of the legs, is in dispute. Some stand up for white or bluish legs, averring that they indicate delicacy of flesh; while others battle for yellow legs, claiming that they bear up the richest and most highly flavored meat. As for ourselves, we refuse to be a party in this strife, but if our table is supplied with a plenty of either color, we shall ever be profoundly thankful!

A Protest against Cramming Poultry.

A correspondent of the *Agriculturist* writes thus: The other day I read an article in a city paper, describing the method by which French fowl raisers *are said* to make an ordinary chicken weigh seven or *eight* pounds. It seemed so absurd I thought nothing of it, until visiting an old farmer in my vicinity, I found him forcing flesh upon turkeys for the holidays, in nearly a similar manner, viz.: by stuffing dough down their unwilling throats until their crops would hold no more, the birds being in close quarters, without possibility of exercise. The French go a little further, excluding light as well as liberty, visiting the captives three times a day, cramming them with pellets of dough and a little lard—in quantities which nothing could have induced them to eat voluntarily. The treatment is continued a month or more, and they occasionally die under it. The description naively adds, 'we should think so'! It is not pleasant to think the unctuous plumptitude of these fabulously fat chickens is blont and disease—there is no other right name for it. There is only one right way to rear animals we design for food, and that the great majority pursue. They eat and drink, and come and go in the pure light and air at will. Every other course is *against nature*, and we are sure no sensible farmer will try the so-called "French" method of adding flesh to his poultry at the expense of the laws which alone can make them really fit for food. Common Sense.

The Family of the Grasses.

GEOGRAPHICAL DISTRIBUTION OF GRAINS.

If any thing on earth exhibits the ineffable wisdom and beneficence of the Creator, it certainly is this family of plants. No other family comprises so many genera, species, and individuals, and no others are so extensively distributed over the habitable globe. We see that the most useful plants are by far the most numerous; and the most widely diffused of these are embraced in the Grass Family, (*Gramineæ.*) The most useful species of this family are: *Wheat, Rye, Barley, Rice, Maize,* or *Indian Corn, Oats, Sugar-Cane, Sorghum,* and *Imphee.* From these plants, as is well known, our bread and sugar are mainly derived. To these genera and species may be added those kinds of grasses on which the whole family of ruminant animals principally subsist, viz: Timothy-grass (*phleum pratense,*) Blue-grass (*poa compressa,*) Red-top (*agrostis vulgaris,*) Panic-grass (*panicum nitidum,*) Millet (*milium effusum,*) Fescue-grass (*festuca pratensis* and *elatior,*) Broom-grass (*bromus pubescens,*) Beard-grass (*andropogon nutans,*) and numerous other varieties of the genera above named, as well as many other genera. The plants are herbaceous, with few exceptions, as the *Bamboo,* which has the hardness of wood. Botanists have enumerated more than 300 species of the grasses in the United States, notwithstanding which, those varieties commonly cultivated here for fodder, are of European origin.

Within the northern polar circle, agriculture is found only in a few places. In Siberia grain reaches at the utmost only to 60°, in the eastern parts scarcely to 55°, and in Kamschatka there is no agriculture even in the southern parts about 51°. The polar limit of agriculture on the northwest coast of America appears to be somewhat higher; for, in the more southern Russian possessions, (57° to 58°,) barley and rye come to maturity. On the east coast of America it is scarcely above 50° to 52°. Only in Europe, namely, in Lapland, does the polar limit reach an unusually high latitude, (70°.) Beyond this, dried fish, and here and there a few potatoes supply the place of grain. The grains which extend farthest to the north, in Europe, are barley and oats. These, which in milder climates are not used for bread, afford to the inhabitants of Norway and Sweden, of a part of Siberia and Scotland, their chief vegetable nourishment. Rye and spelt are the next which become associated with these. Rye is the prevailing grain in a great part of the North Temperate zone, namely, in the south of Sweden, and Norway, Denmark, and in all the lands bordering on the Baltic, the north of Germany, part of northern Russia in Europe, and part of Siberia. In the latter, another very nutritious grain, buckwheat, (*polygonum fagopyrum*) is frequently cultivated. In the zone where rye prevails, wheat is also generally to be found; barley being here chiefly cultivated for beer, and oats supplying food for horses. To these there follows a zone in Europe and western Asia, where rye disappears and wheat almost exclusively furnishes bread. The middle or the south of France, England, part of Scotland, a part of Germany, Hungary, the Crimea and Caucasus, as also the middle lands of Asia, where agriculture is followed, belong to this zone. Here the vine is also found; wine supplants the use of beer, and barley is consequently less raised.

Next comes a district where wheat still abounds, but no longer exclusively furnishes bread; rice and maize, or Indian corn, becoming frequent. To this zone belong Portugal, Spain, part of France on the Mediterranean, Italy, and Greece; also the countries of the East: Persia, Northern India, Arabia, Egypt, Nubia, Barbary, and the Canary Islands; in these latter countries, however, the culture of Indian corn or rice towards the south, is always more considerable, and in some of them, several kinds of sorghum (*Dowra*), and *Poa Abyssinica,* come to be added. In both these regions of wheat, rye only occurs at considerable elevations; oats, however, more seldom, and they at last entirely disappear; barley affording food for horses and mules.

In the eastern parts of the temperate zone of the Old Continent, in China and Japan, our northern kinds of grain are very unfrequent, and rice is found to predominate. The cause of this difference between the east and the west of the Old Continent, appears to be in the manners and peculiarities of the people. In North America, wheat and rye grow as in Europe, but more sparingly. Indian corn is more raised in the Western than in the Old Continent, and rice which is cultivated to considerable extent in South Carolina, Georgia, and in the Gulf States.

In the torrid zone, Indian corn predominates in America, rice in Asia, and both these grains in nearly equal quantity in Africa. The cause of this distribution is, perhaps, historical; for Asia is the native country of rice, and Indian corn is indigenous to America, and probably also to Africa and Asia. It is true that most writers who have mentioned this plant have maintained that America is its native region; but no botanist has ever found it here growing wild; but the Landers found it extensively cultivated all along the river Niger in Africa 500 to 1500 miles from the ocean.

For the American Agriculturist.

Benefits of Rotation.

A correspondent of the Country Gentleman from Wisconsin thinks rotation is unnecessary, from the fact that he has raised potatoes with improving crops each year, for four years successively. This is one of the cases where "a little learning is a dangerous thing." There is no principle better established in modern husbandry, than the necessity of rotation to secure maximum crops. The eminent success of British farming rests upon this practice. It is quite possible that in a virgin soil, the same crop may be grown with success for years in succession. But this does not invalidate the principle. Cultivation soon uses up a virgin soil (except in bottom lands,) and nothing but rotation can keep up their fertility during a long period of time.

On a piece of reclaimed land where we got 220 bushels of field beets in 1860, we this year gathered only 127 bushels. The land had manure enough and careful tillage. The result we have no doubt was mainly owing to a repetition of the same crop. On a piece of garden soil where we gathered thirty eight bushels of carrots in 1860, we raised this year less than twenty bushels. The soil was rich with manure, but had been in carrots four years. On another patch where potatoes had been grown with carrots as a succession crop, for only two years, there was less than half a crop. On another piece of meadow that had been in grass for a generation, potatoes were planted five years in succession. They did very well for three years. The yield the last season was not more than half a crop, though manured broadcast and in the hill. These facts show pretty conclusively that the soil demands a rotation. It may be doubted whether the exception, usually made in favor of the onion crop, disproves the rule. It is well known that wood ashes are a favorite fertilizer for this crop, and that the lime and potash in them are alkalies, and prepare plant food very rapidly for the use of the crop. But even with this aid, the maggot and other diseases are making their appearance in the onion districts, and very much diminishing the profits. May not the trouble be owing in part to the practice of compelling the onion to live upon its own decay, as it must where the same land is used for this crop for a long course of years.

In virgin soils, or those that have lain in grass for a long period, it may be economical to repeat a crop, but as a rule there should be a change of crops every year. Whatever may be the philosophy of the fact, it will hardly be disputed that all crops do better in rotation. Plants seem as fond of a change of food as animals.

CONNECTICUT.

An Englishman on Peat.

In a recent number of a leading British magazine, the Editor grows eloquent over his "newly discovered" uses of peat. He speaks of what the majority of American farmers have long known, as follows:—"Dry peat has been discovered by an eminent agricultural professor of chemistry as a good deodorizer of offensive putrid substances; it possesses the wonderful disinfecting properties of charcoal; and by mixing with common night soil in about equal proportions, makes a valuable manure, not inferior in its results to the best South American Guano." He says that when thus prepared, it may be used as a top-dressing, or be drilled, or dropped in with seed, at the rate of 700 to 800 pounds per acre, and may be used for every known crop, for the garden and for the lawn. Pulverize peat and strew it over the floors of stables, piggeries, or cow-houses, with a thin covering of straw over it, to keep the animals clean, and it will disinfect the buildings and absorb all the liquids which would otherwise waste.

Wherever there is a small nuisance of any kind, a cess-pool, sewer, water-closet, vexatious kitchen drain, etc., treat the same with peat. Let every cottager possess himself of a barrel or two of this article, and his little domain will thrive like a green bay-tree. "From the palace to the hovel, let this grand renovator and purifier be," etc., etc. Our trans-Atlantic cotemporary goes on in a very grandiloquent style.

Fence for Wet Lands.

To the Editor of the American Agriculturist.

The *best* fence which I know of for land that "heaves," is made in panels four boards high, the boards nailed with *twelve-penny clinch* nails, to three strips of white pine plank (1¼ or 1½ inches thick. The panels are held up against the posts by binding with number 8 *annealed* wire. No middle post is required. If hemlock boards are used, a brace and bit are necessary to bore through the boards at the ends, to prevent splitting. The posts being sharpened when set, they can be driven back if they heave, without injury to the fence. The above is from an experience of nine years with different kinds of panel fence. It is easily and quickly made, is cheap, not patented, and is the *best* portable fence I have ever seen, if I did invent it myself.

I have also tried all sorts of ways for nailing

boards and plank to fence-posts, and have become satisfied that where service and not show is required, the *best* manner is as follows:

The above is a vertical view—looking down at the top of the fence. R. M. HASBROUCK.
Saratoga Co., N. Y.

Horses Injured by Hungarian Grass.

As has been previously stated in the *Agriculturist*, from all the evidence received, there appears to be no peculiar property in millet or Hungarian grass which makes it hurtful to horses, or other stock; but injudicious feeding of the ripened seed with the stalk may be injurious. The following item from the Prairie Farmer refers to this matter. A gentleman having grown and fed considerable of this grass to his stock last season, several of his horses beame stiffened and almost useless. One, a fine mare, died. To ascertain what ailed her, he opened and examined her thoroughly, and found in her stomach a ball of Hungarian grass seed, weighing from seven to eight pounds, so hard as to be broken with difficulty. Acting on this discovery, he gave his other horses a dose of castor oil, and very soon, masses of seed were passed from them, apparently parts of the balls described, some pieces as large as hens' eggs.

If this be the difficulty, it may be prevented by steaming the grass and seed before feeding. As is well known, grain of any kind reaching the stomach unbroken by the teeth, is not easily digested, and whole kernels of corn or oats may often be found in the excrements of animals, as the poultry testify by assiduously scratching over the manure heap. Millet seed of every variety is so small as to be masticated with difficulty, and most of it will enter the stomach unbroken. Thorough cooking by steam will swell and soften the kernels, and prepare the grain to be readily acted upon by the gastric juice in the stomach of the animal. *

Diseases from Ammonia in Stables.

Nothing is more common than diseases among cattle, especially horses, arising from foul stables. Horses are more troubled with it than cows, probably from the fact that their dung is generally richer and undergoes a more rapid fermentation, throwing out ammonia in large quantities. In a close stable the gas is so strong that the eyes are painfully affected with it. This is an alkali, and is classed among the most powerful stimulants, the constant respiration of which, predisposes to affections of the lungs. The strength of the gas may be judged from the odor that arises from a common hartshorn smelling bottle. In many stables no provision whatever is made to guard the animals against this subtle poison. The floor is always saturated with urine, and the pungent odor of this gas is always present.

There are many cheap experiments within the reach of most farmers to prevent this nuisance, and to save the ammonia for the manure heap. As all the animals are now coming to the stables, particular attention should be paid to this item of economy. Common ground plaster is a good absorbent, and a few quarts sprinkled daily in the manure gutters, will keep them sweet and clean. Sawdust from the shingle and saw mill will make good bedding, and if renewed often enough, will retain all the ammonia. In most mills in the country, this article accumulates, and has to be thrown into the stream, to get rid of it. It may be turned to profitable account for bedding.

Some farmers living near tan works, use the spent tan bark for this purpose. If kept under cover and used in the dry state, it makes a very valuable manure. Shore farmers have an unfailing resource in sea weed, particularly the eel grass. If this is spread and dried upon the shore it makes a good bed, and has great power of absorbing gas. Better still is dry muck and peat kept housed for the purpose. A half cord of this under a horse with a little changing where the water falls, will keep a stable sweet for two weeks. This is within reach of most farmers, and is, perhaps, the cheapest and best method of enlarging the compost heap. Leaves gathered from the forest, or straw, make a suitable covering for the muck at night, and keep the animals clean. As ammonia is the most valuable constituent of the manure heap, it ought to be a point of honor with every cultivator not to have an ounce wasted. It is the very life of his business—good for the eyes of potatoes, beans and other plants, but very bad for the eyes of horses and cattle.

For the American Agriculturist.

Saddle Horses.

The present war times have given new value to saddle horses. They are wanted for military service, and then the prevailing martial spirit has caused our young men and maidens at home to learn and practice the noble and robust accomplishment of riding on horseback. Luxuriously cushioned and closely curtained carriages may do for the feeble and the effeminate; but to the young and strong, give the saddle and the bounding steed.

Aye, and more than that: the saddle is just the place for the feeble who wish to become strong, and who have the courage and perseverance to take this daily regimen. We speak what we have tried and do know, that for a pulmonary complaint, nothing is better than daily exercise on horseback. If the weather is cold, put on more clothes; if wet, then throw on a rubber overcoat; but sally forth once a day, and Dobbin will bring you home in better health and spirits than when you went away.

There is a great difference in horses. Some were born for the saddle, and are easily trained to it. Some are naturally awkward, long-paced, high stepping, making it a penance to ride them. Others again can be broken to the saddle only by careful training. With the latter, the work should be begun early. Care should be taken that a young horse get no fright by throwing on the saddle rudely, or by the rider's mode of mounting and dismounting. Vex him not by unnecessary roughness in putting the bits into his mouth. Let him not get the habit of starting suddenly at pokerish objects by the roadside; for a saddle horse, this is one of the worst of faults. And when he does get frightened, do not try to whip him out of his alarm; he will be all the more terrified next time.

Some horses have a good deal of style and carriage by nature; with others, it must come chiefly from training. Keep your horse from throwing his head very high, or dropping it very low. A little curve of the neck is very graceful. An ordinary snaffle-bit with a martingal enables one to manage the head successfully. In certain cases, it will not; and then the curb bridle must be resorted to. An occasional use of this will bring down a lofty head and an outstretching nose. And then, contradictory as it may seem, the same bridle skillfully used, will bring up a doggishly low head. But such a bit should not be used constantly, or it will lose its value.

The gait of a saddle horse is somewhat a question of taste, but a slow, easy gallop is, on the whole, the most popular. The natural gait of a horse (trot, pace, or gallop,) will be the easiest for him and his rider. A little management, such as tightening or loosening the rein, a motion of the legs or of the person, a slight whistle or chirrup, will soon be understood by the horse, and cause him to take the gait or speed desired. EQUESTRIAN.

A Harnessing Arrangement.

A correspondent of the Country Gentleman describes the following method of harnessing and unharnessing a horse to a single wagon: "In the first place, my harness is made with the collar open at the bottom, and no buckle, but the hames are fastened to the collar, and there is one buckle to fasten them both. The tugs and hold-back straps are not unhitched; the lines lie over the dash, where they will not get under the horse's feet; they may be unbuckled from the headstall, or remain with it, and all hang up together. I have a wooden hook, like an ox-bow, with half the length of one side cut off, so as to hook under the back saddle, collar, and headstall. A cord is attached to the long end of the hook, and put up over a pulley, and through another pulley, and down to about three feet from one side of the horse. Unbuckle the belly-bands and the hame-straps, put under the hook, pull all up, and make the cord fast to a small hook at the side of the carriage house. A horse will soon learn to place himself back into the breeching, when the harness and shafts are let down, three or four buckles are fastened, and he is harnessed."

Breaking Heifers for Milking.

This is often made quite a serious affair, in which kicks and bruises are freely interchanged between the frightened brute and the irritated master. Many an otherwise excellent milker is spoiled for life by harsh treatment. A heifer, if well broken to the milk pail, is thereby made worth at least twenty per cent more—an increase which will pay for much painstaking. Harey's reasoning respecting horses applies equally to other animals. They only resist when injury is apprehended, and their natural instinct suggests danger whenever any unusual treatment occurs. Every one has noticed how shy a creature is in entering strange enclosures, or at sight of new objects. The handling of a heifer's bag is to her a very unusual proceeding, and, in addition, the teats are often tender, and the bag caked and inflamed so as to be painful under even a gentle touch. Training for milking should commence long before calving. First teach the animal to welcome your coming by little presents of an apple, a handful of corn, or salt, or other delicacy. She will soon readily permit the hand to be laid upon her back and enjoy the gentle rubbing and scratching which may be given. Extend the handling to different parts of the body, until she will not flinch from grasping her teats, and the work may be soon accomplished without even a harsh word. This will be a good lesson for the boys to practice the present month, and teach *them* patience and kindness, in addition to the good effects upon the animals.

[PRIZE ARTICLE.*]

Winter Feeding and Care of Animals.

BY "BURICOLIST," OF ONTARIO COUNTY, N. Y.

"'Tis then the time from hoarding cribs to feed
The ox laborious, and the noble steed;
'Tis then the time to tend the bleating fold,
To strew with litter and to fence from cold."
DAVID HUMPHREYS.

I consider it self-evident that to winter stock *properly* and profitably, we must have at hand the *means* of doing so, viz: the proper quantity and kinds of fodder, and convenient buildings. It would, however, be out of place here to enter on the subject of farm buildings, as there is no telling how far it might lead us.

The first point to be secured is the *health* of the animals, and for this sufficient room and good ventilation are indispensable. Warmth is less important to stock than ventilation, and as yet the great mass of our farmers are not awake to the importance of ventilating even their own *houses*. All barns and stables need *ventilators*, as outlets for the foul air, and the same should by all means be provided for every building which is used for live stock of any kind. Where ventilators from stables pass

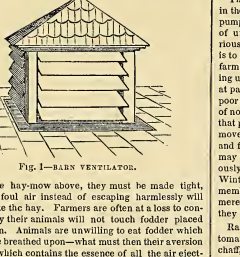

FIG. 1.—BARN VENTILATOR.

through the hay-mow above, they must be made tight, or else the foul air instead of escaping harmlessly will contaminate the hay. Farmers are often at a loss to conjecture why their animals will not touch fodder placed before them. Animals are unwilling to eat fodder which others have breathed upon—what must then their aversion be to that which contains the essence of all the air ejected from the lungs of ten, twenty, or thirty animals.

[Ventilators need protection from the weather and uninterrupted escape for the air. Fig. 1 shows a common and good form. Fig. 2 is Emerson's ventilating cap—a form for the end of a ventilating trunk carried out above the roof; it is made of "galvanized" or zinc-coated sheet-

Fig. 2.

iron, and crested, when there is a little wind, a strong draft.]

Next in importance to ventilation is *room*. A false idea of economy prompts many to crowd their animals into half of the room they require. It is far better to err the other way. There are many days during the winter when the weather will not warrant our turning stock out any longer than may be necessary to water them and to clean out their stables; and when we not only deprive them of exercise, but cramp them up in stables so that they have hardly a chance to move either way, we can not expect to meet with success in winter feeding.

Warmth is desirable in farm buildings, provided its introduction in no manner interferes with the perfect ventilation of the same. It makes but little matter how tight you make the floor, sides and roof of your stable, provided there be an ample supply of fresh air and a proper outlet for the foul. The animal heat, from the stock, will make a warm stable if the cold blasts are shut out by matched siding or battens, and the ice and snow kept from intruding under the eaves and through the cracks in the roof. Paint must be used carefully around buildings—cases of death from licking fresh paint are by no means rare. Farm buildings should be convenient, and although roomy, they must be compact or else many steps will be taken that might otherwise be avoided. Have your hay, meal and roots close at hand so as not to carry them far. Not only is time wasted in so doing, but in the course of a season a considerable amount of hay and most of the heads and seed, which the cattle like best, are lost. I regard the straw and root-cutters indispensable tools to every economical farmer. As for root-cutters I have never seen an American-made one that did the work to suit me, but I know of one imported from England which is all that can be desired except in price ($50).

NEAT CATTLE.

In speaking of the wintering of cattle, we of course refer to their treatment from the moment they are put up in the stable in the Fall until they are turned out to pasture in the Spring. Pasture generally grows short for cattle, especially milch cows and cattle which it is intended to fatten during the Winter, as soon as September. When this occurs, a little hay and grain should be fed, even before it becomes necessary to confine the stock to the stall, and as pasture gets more and more scanty the feed should be increased by degrees, until it is time to shut them up. In spring do not turn out early; they will injure the growing grass, while it will be insufficient for their wants and yet destroy their relish for hay.

We have then to consider the treatment of milch cows, breeding cows, fatting cattle, oxen and calves, from September to May—seven long months. What shall we feed them, and how shall we feed them, in order to promote their growth and health, and to atone for the loss of free exercise and fresh vegetable juices which they have during the summer?—A question which, well pondered, will dispel the illusion that it does not pay to winter cattle.

The first fall-feed cattle usually get, is pumpkins fed in the yard, and eaten, seeds and all. This is all wrong—pumpkin seeds are diuretic, that is, promote a secretion of urine, in fact, a regular medicine and therefore injurious to a healthy animal. The tendency in milch cows is to reduce the secretion of milk, and the unrelenting farmer will be surprised to find his cows suddenly "drying up." Cattle which have access to pumpkins when at pasture will neglect the grass and will inevitably grow poor as the pumpkin does not contain the requisite amount of nourishment to supply their wants. I therefore hold that pumpkins, if fed at all, should have all their seeds removed and should then be passed through the root cutter and fed with hay, straw, or stalks and grain, as the case may be. Any falling off in flesh in the Fall is to be studiously avoided, and if allowed to run down in the Fall or Winter it will take a long time for them to recover. Remember the adage, "cattle well wintered are half summered." As soon as cattle are put in winter quarters they require the constant attention of some one man.

Racks provided for yard feeding, although it is not customary, should have *tight floors* so that cut hay, straw, chaff, pumpkins or roots may be fed without waste. It is often necessary to move the racks during the Winter in order to spread the manure evenly over the yards and to keep them at the proper level; and owing to the difficulty of finding clean places to set them down, the floored racks are of great advantage as the food placed on them is not rendered disagreeable to the animals by the gases exhaling from the manure beneath. Fig. 3 is a plan of the style of rack I have adopted and which I consider the best of the many styles in use. The corner posts should be 4 inches square and the braces stout inch boards—the boards should be nailed on the inside and with wrought nails clinched so that in throwing their heads around, as cattle are apt to do when eating, they may not force any of the boards off as they would be likely to were they nailed on the outside. Pieces of two inch plank nailed across the ends support the floor which is of inch boards.

The general rule is to give the poorest feed first and so keep gradually improving—and it is a good rule so far as it goes; but to take cattle up in the Fall and give them nothing but coarse dry straw is absolutely cruel. As for young growing stock they should have the best fodder the farm produces all the year round. Remember that the

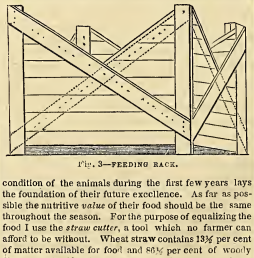

FIG. 3—FEEDING RACK.

condition of the animals during the first few years lays the foundation of their future excellence. As far as possible the nutritive *value* of their food should be the same throughout the season. For the purpose of equalizing the food I use the *straw cutter*, a tool which no farmer can afford to be without. Wheat straw contains 13½ per cent of matter available for food and 8½ per cent of woody fiber and ash; if fed alone therefore it requires a large amount to furnish the requisite nourishment. But if cut up and mixed with hay, roots and meal, it will not only go to nourish the animal, but the very woody fiber, before useless, will counteract the effects of the otherwise too concentrated food. As, however, this kind of feeding can not be managed well unless each animal is fed according to its age, condition, etc., it becomes necessary to provide separate mangers for each. Will our farmers never learn the *profits* of stabling cattle? Except here and there one, they leave their cattle in open yards, or worse yet, in open fields to shift for themselves, throwing them

FIG. 4—STALL FASTENING.

daily, bundles of corn stalks or straw, and giving them access to a trough full of ice, which they call water. Did they but know what an increase of milk they would obtain (one third more at least,) that shelter is cheaper than fodder, and that manure thus made under cover is much more valuable than that which is washed and wasted by every storm, they would, I am sure, immediately change their practice.

The shape and size of the stall is a matter about which every one has his own notions, as also about the best mode of fastening the animals therein. Of all fastenings I consider wooden stanchions the worst, for, besides galling the animal's neck, they prevent its moving its head either way and in fact almost preclude *all* motion. The form of fastening which I like best, is a bent iron rod attached to the side of the stall, as shown in the annexed sketch, (Fig. 4). On this is a ring sliding up and down, to which is attached a chain which goes around the animal's neck. *Two* rings, or links rather larger than the rest and placed side by side allowing the "*key*" to pass through each, make doubly sure, (Fig. 5). This two-ring arrangement is an invention of my own, but it is so simple that I doubt not others have made use of it long ago; I feel sure that no one who has is troubled with cattle getting loose.

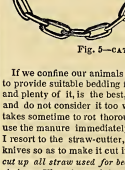

FIG. 5—CATTLE CHAIN.

If we confine our animals to stalls it becomes necessary to provide suitable bedding for them. Good clean straw, and plenty of it, is the best, if you have enough to spare and do not consider it too valuable for this purpose. It takes sometime to rot thoroughly and we often want to use the manure immediately. To obviate this difficulty I resort to the straw-cutter, and taking out two or three knives so as to make it cut in lengths of 3 or 4 inches, *I cut up all straw used for bedding*. The advantages are obvious. There is much less waste of bedding in cleaning out the stable. Cut straw absorbs liquids much more readily and consequently rots rapidly. As soon as the clover seed is thrashed, (and we usually try and thrash it as early as possible so as to save the wheat, oat and barley straw), I use the clover chaff for bedding and find it superior to almost anything else. The clover straw not fit for feed is cut up and used for bedding. Spent tan-bark, sawdust, and even muck, are all good bedding materials, but bedding of some kind I consider necessary for the health and comfort of animals, and have set my face against "*sparred floors*," Alderman Mechi, 'or any other man,' to the contrary, notwithstanding. The quality of the manure is a matter of no small importance; let any one try my plan for the thorough incorporation of long and straw, and see if the results will not pay better than those obtained from coarse straw which forms the chief constituent of nine tenths of the manure made hereabouts.

With our cattle well bedded, sheltered and furnished with plenty of pure air, we need but one more thing to put them in a state in which every ounce of food will "tell." This one thing needful is an external application composed of:—Curry-combum, Thorough-brushum, Elbow-greasum, of each *q. s.*, mix and apply in early morning daily. The cards and curry-combs must be kept moving. Cattle need and profit by their use fully as much as horses, even in Summer. Cattle *must* be kept clean; filth, and irritation from impurities and vermin, cause them to lick themselves inordinately, and the hairs, thus taken into the stomach, in time form compact masses which sometimes destroy the animals. If you have never tried it, you will be surprised to see how it will improve an animal's looks as well as its health. All animals

* The Committee to whom was entrusted the examination of the Essays on Feeding and Care of Animals, after careful examination unanimously decided to award the prize of $20 to "Buricolist." There were several other very good articles offered, but this is the clearest and most complete.

like it and it is good for all, from man down wards. It also accustoms young cattle to being handled and helps to make them kind and gentle. Besides, it acts as a preventative against lice. Should these pests appear, I recommend alcohol rubbed in along the back and infested parts; if very strong it should be diluted with water.

The straw-cutter has a busy time of it with me. As I have already hinted, I cut up every thing, both bedding and feed; straw, hay and corn stalks, all have to pass through the cutter. I found this paid when it cost me $5 a day to hire it done, and I have since found that it pays still better now that I have a machine of my own. I use straw with hay or stalks, and prefer mixing as it is cut, for I can do the work much more thoroughly. The mixture should consist of two parts or more of straw to every one of cornstalks or hay. The straw keeps the pile from heating, for which purpose, as also for the bene-

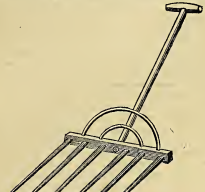

Fig. 6—CHAFF FORK.

fit of the animals' health, an occasional handful of *fine* salt should be scattered over it. Be careful not to cut too much at once, as I have several times done and lost my whole pile of feed in consequence.

The animals will do better for an occasional change from hay to cornstalks, and vice versa, it helps keep up their appetite; this may also be done by changing from one kind of hay to another—from clover to timothy, from timothy to Hungarian, and so on. For handling cut feed I find a chaff fork very convenient. Any farmer can make one with a drawing knife and three-quarter-inch auger (Fig. 6). The handle should be 3 feet long and put in rather slanting; the tines are 2 feet long and 3 inches apart; the bows are of hickory, steamed and bent. Such a fork will take up a bushel or more of chaff or cut feed at once, and will be found useful for many purposes.

Do not feed too much at a time; feed often and in small quantities, and always let the last meal be eaten up clean before you give another. Give the first feed early in the morning—cattle are early risers and need early breakfasts. Have a good sized trough to mix your feed in and keep it scrupulously clean. Pour into this the number of baskets full of cut feed necessary, then throw in the allowance of cut roots and meal and incorporate the whole with your *hands*; hands were made before scoop shovels, and you can mix it more thoroughly, and *feel* when it is mixed.

For root feed I use beets or mangel wurzels, as I find I can obtain a larger yield of them per acre; the cattle seem to like them as well as any, if not better; they seem capital for fattening stock, and tend to produce milk in cows without imparting any unpleasant flavor to the milk. Their watery nature, however, necessitates a free mixture of dry food, and they have the disadvantage of making the butter look white. To remedy this I mix a few yellow carrots with the feed given to milch cows. Linseed cake ground, I think, makes the best meal, but the supply in this part of the country is limited, and corn and oats, in the proportion of two parts of the former to one of the latter, ground fine and even, I find makes a very good substitute, and as every farmer raises these two staples he will find it far more profitable to grind and feed than to sell them. For young stock I add to this mixture 4 qts. of pure flax-seed to every bushel of corn. The steaming of food, is a matter on which, I am sorry to say, I have no experience, but incline to the opinion that it will not pay for ruminating stock, especially where the matter would have to be placed in the hands of hired help. The danger arising from fire around buildings and the expense of fuel as well as the first cost of the apparatus, all combine to make me think that the operation will, perhaps, not pay, and if the feed is properly cut and mixed with roots, I feel inclined to risk the digestive powers of the animals to do the rest of the work without help.

As to the proper quantity to be fed to each animal, it is impossible to lay down any fixed rules. Some will starve on what would surfeit others. Milch cows will do well on from 3 to 6 quarts of meal, 2 pecks of cut roots, and 2 bushels of cut feed daily. Working oxen and fattening cattle will require an increase of meal, say 4 to 8 quarts, and a bushel of roots, whereas young stock require but a limited supply of meal and a half bushel of roots per day. Individual animals and the different breeds will differ greatly, and experience and watchfulness alone can make a successful feeder. The rule should be, to feed enough, but to beware of the other extreme; if an animal once gets cloyed it will receive a check which a month's feeding will perhaps fail to obliterate. Clean water with the ice carefully removed should be given three times a day. *Rock salt* should be placed in calf-pens and yards; the animals like it, and it promotes their health.

It is a common practice with many to manage their breeding cows so as to have them come in at the beginning of Winter as they then have more time to attend to the calves. This is, however, not judicious. The foundation of future perfection in animals is laid the first year, and especially in the change from milk to vegetable food, and the most delicate and tender kinds of grass should be selected and introduced in the calf-pen when the animal is a month and a half or two months old. As we seldom have grass fit for the purpose before the middle of April I endeavor to have the calves come in about the middle of February or the first of March, and generally drive the cows to bull as near the first of May as possible, allowing 283 days for them to go with calf. Heifers should not be driven to bull until they are nearly if not quite three years old. My practice is not to allow the calf to suck the cow at all, as it is more difficult to teach it to drink afterwards, and the cow misses the calf a great deal more if it is allowed to suck her even once. As soon as the calf is able to stand I milk the cow and putting milk on my fingers in the calf's mouth I hold his head down to the milk with my other hand, when he begins to suck I gradually withdraw my fingers. Sometimes a calf will learn to drink at once, and at other times it will never learn. For the first week the calf should be fed three times a day—as much but no more than it will take and seem to relish. The next three weeks warm new milk should be fed twice a day, and after that, plenty of warm scalded milk with fine oil or corn meal for two months longer, gradually tapering off towards the last so as to wean the animal when four months old. If you have patience to do it, it will pay to boil the oil meal in water, say half a pint of meal to a quart or more of water, and then mix the whole with the scalded milk. This porridge requires constant stirring to prevent its burning; it will, however, hardly pay to make it unless you have calves enough to make it an object to use an agricultural furnace. Bull calves not needed as bulls should be castrated when *one month* old. The ordinary way of doing this is by cutting. A simpler if not a better way, however, is to tie a string firmly around the scrotum near the body. In two or three weeks it will fall off of itself, and will heal far more readily than in any other way. Only the best calves should be selected for raising, and after you have once made up your mind which to keep, no offer from the butcher should tempt you; surely they are worth as much to you as to him. I have sometimes been troubled with calves having the scours; in such cases I have always found a raw egg or a little wheat flour mixed with the feed, and accompanied with careful management, a safe and sure remedy.

Begin to break calves when they are a month old by leading them in and out of their pens—if you take them young they will soon learn, and will never forget it, and the convenience of the practice must be tried to be fully appreciated. If you put it off too long, the first thing you know the animal will be stronger than you are, and you will have a hard job of it, if you succeed at all. Don't jerk and slash. Go gently but firmly—have a regular halter made small enough; if you depend on a strap around the neck, the animal will be very likely to get the start of you, which should by all means be avoided. If it succeeds once you may be sure it will try it again. It is a good practice to begin tying them up when young.

Great care should be taken to milk cows clean—do it three times rather than once a day; the less they are milked the sooner they will dry up. See that the milkers do their duty *in silence*, and let the milking be done *white the animal is feeding*. Be careful not to expose cows to drafts which may give them a cold and result in garget or inflamed udder. In case such an accident (?) should occur, a few drops of tincture of *Aconite** in water, and a piece of bread soaked therein and applied, is about as good a remedy as any. Steers intended for working cattle should, of course, be trained early—the more they are handled the better, and if possible they should be taught by the same man that is afterwards to have the management of them. Patience and perseverance are requisite. Working cattle when first put to work in the Spring become easily heated and liable to colds; do not put them at too heavy work at first and keep them out of drafts; in the Spring they are better kept up until the heavy labors of the season are over. Oxen have now fallen into total disuse in many parts of the country, but for many kinds of work they are fully equal if not superior to horses, and I regret that the limits of this article will not allow me to dwell upon the advantages that would result from their use.

* A very deadly poison and to be used with great caution.

THE SHEEP-FOLD.

"Now sacred Pales, in a lofty strain
I sing the rural honors of thy reign.
First, with assiduous care from Winter keep,
Well foddered in the stalls, thy tender sheep."
DRYDEN'S VIRGIL.

Although sheep, to thrive, need a range, *shelter* at night and during storms is fully as important, if not a great deal more so for them than for any other kind of stock. The reason of this is obvious. Nature has provided this animal with a thick, warm covering of *wool*. Now, although wool contains a certain oily substance, meant to prevent water penetrating through it, yet if long exposed to rain or snow this proves insufficient, and the wool becomes soaked, and, from its spongy nature, when once wet, stays wet, and often gives the animal a cold which terminates its existence. To prevent this calamity we must provide shelter for them. A good shed and a yard inclosed by a tight board fence placed so as to get the full benefit of all the sunshine, are requisite to winter sheep.

I annex a diagram of a sheep shed, (Fig. 7 & 8,) planned for my own use. The back and sides are boarded tight, and the front is composed of a series of swinging doors which may be hooked up in the day time and let fall at night. The floor has sufficient inclination for drainage. A feeding rack runs along the back from end to end, small doors from the outside affording a ready means of introducing hay into it. There are two or more ventilators in the roof and numerous *inlets* for air provided near the floor. The roof in front should come down to within four feet of the ground and be provided with a gutter. Such a building 10x30 would afford accommodations for fifty to

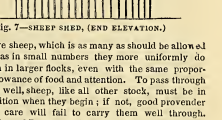

Fig. 7—SHEEP SHED, (END ELEVATION.)

seventy five sheep, which is as many as should be allowed to a flock, as in small numbers they more uniformly do better than in larger flocks, even with the same proportionate allowance of food and attention. To pass through the winter well, sheep, like all other stock, must be in good condition when they begin; if not, good provender and extra care will fail to carry them well through. After the first of December they should no longer be allowed to ramble over the fields, as it is poor economy to expose them to the inclemency of the season for the sake of what little food they can pick up. As early as October I begin feeding them a moderate allowance of roots, beets being as good or better for this purpose than

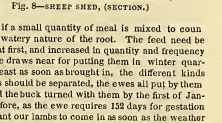

Fig. 8—SHEEP SHED, (SECTION.)

any other, if a small quantity of meal is mixed to counteract the watery nature of the root. The feed need be but small at first, and increased in quantity and frequency as the time draws near for putting them in winter quarters. At least as soon as brought in, the different kinds and breeds should be separated, the ewes all put by them selves, and the buck turned with them by the first of January or before, as the ewe requires 152 days for gestation and we want our lambs to come in as soon as the weather is settled in the Spring. The lambs and wethers should also be separated and divided in flocks, of which each member shall be as near of a size as practicable, so as to prevent the stronger from taking the lions share.

Sheep will sometimes have diarrhœa when first put in to grass, and fed on roots and hay; when potatoes are fed raw this will be almost sure to occur, as they possess loosening properties, and should never be fed in the early part of the season unless cooked. If diarrhœa shows itself it must be checked at once by administering a scruple of opium and two or three ounces of castor oil every other day, or if discovered soon enough, a dose of 2 pints of scalded flour two or three times a day will perhaps be better

Should sheep catch cold from exposure, and discharge matter at the nose, a little tar or pitch from pine boughs is the remedy. Should foot rot show itself, my remedy would be to sell out and turn to some other branch of stock raising, although John Johnston, the veteran tile drainer and sheep feeder, recommends paring the hoof and rubbing into the sores a salve of blue vitriol and lard.

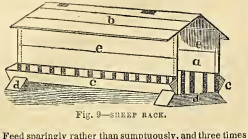

Fig. 9—SHEEP RACK.

Feed sparingly rather than sumptuously, and three times a day. Sheep delight in a change of food. Clover hay is perhaps better adapted to them than to any other animal, and from the large amount of nitrogen it contains will greatly enhance the value of their manure. An animal weighing 100 lbs. will consume about 3 lbs. of clover hay or its equivalent per diem. Straw may be substituted for hay as a change, the quantity being increased. A fat sheep will not consume as much in proportion as a poor one, and it will need no grain. Sheep should therefore never be allowed to fall off, and as soon as one becomes thin it should be at once removed to the hospital and fed well until it recovers; if once it reaches a certain point it will be past recovery.

Racks for feeding hay and straw should be upright, so as to prevent the seeds from falling into the wool about the neck. Fig. 9, is a section of such a rack. The hay is placed in the space *a*, and covered by the roof or lid *b*; *c*, *c*, are troughs to catch the seeds from the hay and for feeding meal, etc.; *e*, *e*, are tight boarded sides, and *d*, is a solid square piece of timber at each end which makes the whole thing set solid on the ground. Sheep *must* have water when confined to yards in Winter. In Summer they feed when the dew is on, and thus get the name of living without water, but the idea is erroneous. If your hay is not well salted, place a lump of rock salt in the yard where they can lick it; let nature regulate the quantity and they will not take too much.

Wethers which are meant to supply the winter market should be kept in the dark, and great care taken not to disturb them when feeding—they will thus be quiet and naturally lay on more flesh. Let them have a gallon of cut potatoes or beets every day, ½ or ¾ lb. of oil cake meal, which is superior to any other for sheep, and plenty of good bright clover hay. To each and handle them, carefully drive them into a small pen and you will accomplish it easily and without heating and exciting them.

A month or six weeks before ewes are expected to yean give them somewhat more food, being careful, however, not to get them in too high condition and thereby increase the risk in yeaning—½ gill of Indian corn a day to each is a good allowance. As the time draws near, give them warm shelter and plenty of bedding at night, and watch them closely so as to assist nature if necessary. Be careful what you feed in the shape of roots; turnips are said to affect the milk and injure the lambs. A part of potatoes or beets will not be out of place. Should they refuse to own their lambs, shut them by themselves till they will. If a ewe dies, feed its lamb with fresh cow's milk, and should a lamb of the same age die, clothe the orphan with its skin, and if not bloody, the ewe will at once take to it. Buck lambs should be castrated when from two to four weeks old, as the weather will allow. A simple incision made on either side for this purpose will heal most rapidly, but as this does not always afford sufficient outlet for the blood, it is best to cut off the whole lower portion of the scrotum.

PIG STY.

Of all farm stock, hogs are perhaps the most indispensable on account of their nearly omnivorous nature, and the ease with which they appropriate the refuse of the farm that would otherwise be lost. Hogs need a building for their accommodation as well as every other kind of stock. This may be small or large, as the means of the builder and the number of animals he may intend to confine dictate. A simple inclosure with a few boards placed across one corner is the simplest form of pen, and from that up to the magnificent piggery erected by Earl Egremont of England, there are of course many gradations. For confining hogs in Winter, a covered inclosure, if properly ventilated, is best. For sows and boars this will need to be larger than for fattening hogs, which latter only need room to move around. A plank or stone floor is essential for the sleeping apartment at least, for the sake of cleanliness and ease in throwing out the manure, a "chore" which should be attended to daily. It will also save a great deal more of the manure which is of more value than any other made on the farm. The hog is an uneasy animal; every thing about his dwelling must be made tight and strong, or he will give much trouble, by once in a while "breaking cover." Where practicable, stone walls are the best inclosures. When a building of considerable size is erected, it should have a cellar underneath for the purpose of storing roots, potatoes, etc., and meal bins and a corn crib overhead. (Figs. 10, 11, and 12). A good thick brick chimney and one or more ventilators should also be added. Iron or thick plank troughs, securely spiked to the floor, and an agricultural furnace are the necessary furnitures. Every mouthful of food should be cooked. In this part of the country we begin fattening hogs as soon as we begin to husk corn. The *soft* corn and *nubbins* are the principal food for about 3 weeks or a month, when hard corn, shelled and cooked, or what is still better, very thick corn meal gruel is substituted and continued until the animal is slaughtered. It is better to begin feeding in September as soon as the corn is cut, and the pumpkins can be got at, as the latter are excellent for hogs and enable us to *begin* fattening before the early frosts. An occasional mixture of charcoal with the food greatly strengthens and stimulates the digestive powers. This is undoubtedly the best way to make pork, but to feed

Fig. 10—PIG STY WITH CORN LOFT.

for market, corn is often worth too much; and although the particular flavor of corn-fed pork is easily distinguished and appreciated, yet it will seldom pay. Beets are hardly nutritious enough for fattening hogs, though they form a very good food for pigs from 3 to 4 months old; they are injurious to pregnant sows and to small pigs. Turnips or carrots, if boiled or steamed, do very well; but potatoes cooked and mashed, are superior to all other

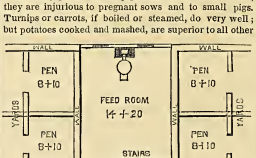

Fig. 11—GROUND PLAN OF STY.

food of this class. It will not pay to feed hogs long after the first of December. If properly managed they will then have laid on all the fat they are capable of.

The period of gestation in these animals is about 120 days, and, if properly managed, 5 litters may be produced in two years, varying from 5 to 16 pigs at a litter. It is very difficult to rear winter litters on account of the extreme susceptibility of the young animals to cold. We should therefore manage so as to have sows farrow early enough in the Fall, or else late enough in the Spring, that the pigs may be out of danger of severe cold. November is as soon as the boar should be turned in for spring pigs. Breeding sows need close watching when about farrowing both for assisting nature, if necessary, and to prevent their killing their young by lying on them, as they often do.

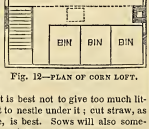

Fig. 12—PLAN OF CORN LOFT.

On this account, also, it is best not to give too much litter, as the young are apt to nestle under it; cut straw, as recommended for cattle, is best. Sows will also sometimes devour their young, and should have a small allowance of animal food, with ashes and charcoal, to satisfy their cravings. The young should be weaned when six or seven weeks old, and fed skim milk and swill until we are ready to fatten them.

Hog yards should be well covered with muck, chaff, or straw, so as to absorb all the manure. Muck is perhaps best, as it absorbs and retains most manure. No animal loves cleanliness better than the hog, and it is in fact necessary for its welfare, as the gross food it lives upon renders it peculiarly liable to attacks of vermin and diseases of the skin. Even brushing and carding them is beneficial and perhaps profitable.

THE HORSE.

Shelter, pure air, light, and care, are more necessary to the welfare of the horse than to any other animal, and if neglected he will show the effects much sooner. Horse stalls must be roomy, especially for breeding mares—six feet is about the right width. They must be well drained, the floor having a slight inclination to the *center* of the stall, where a grate communicates with a short drain connected with the main drain that runs the whole length of the stable, allowing the urine to escape readily. The floor should be tight, both for the purpose of saving the manure and to protect the horse from the cold drafts from beneath. No slide or rack should be permitted by which the horse will be annoyed by the dust from the hay; nothing will tend to give a horse the heaves so soon as this. Horses should be tied in the center of the stall, or they will be liable to drive more on one rein than the other. A report of the London Omnibus Company, shows clearly the value of cut-feed. "They use 6000 horses—300 are fed 16 lbs. *bruised* oats, 7½ lbs. *cut* hay and 2½ lbs. *cut* straw daily each, and the other 3000 with 19 lbs. unbruised oats, and 13 lbs. uncut hay apiece daily—making a weight of 36 lbs. fed to the first, and 32 to the second, and there was no difference in the amount of work performed—a reduction of the two, making a saving of 6 lbs. per day in feeding each horse, estimated at 5 cents a day, or $300 a day on the 6000." Unthrashed oat straw run through a cutter and mixed with cut hay forms a capital food for horses. Clover (as usually cured) is perhaps the most objectionable hay for horses, on account of its dust which will inevitably result in the heaves, unless it be thoroughly wet. If fed uncut, it should be wet and shaken up before putting it in the manger, and every stalk is thus moistened enough, which is not the case where it is put in the manger and a little water sprinkled over the top. If cut, it should be mixed with straw and roots or meal in the feed-trough, and the whole wet thoroughly. I could never succeed in making horses eat beets, although they are said to eat the yellow best if mixed with chaff. Carrots are the best for their use, and every farmer should raise a sufficient quantity to afford his horses a moderate allowance through the Winter. The sleekness they impart to the coat, and the improvement in the spirit of the horse, will amply repay the time and expense.

Condition powders are sometimes given to horses to help the heaves and improve their looks; they are hurtful, however, as they render the animal liable to take cold. The best condition powder I know of is an application of the currycomb and brush two or three times a day. Never attempt to clean the animal when eating, as it makes him inclined to bite and kick. The best way is to have an open shed where you can fasten him while he is groomed. The comb should be used rather lightly, as the horse's skin is tender; a thorough brushing should succeed and be followed by a good rubbing with a woollen cloth. This may seem a good deal of work, but it will pay. Horses when put to farm work should be groomed every night to alleviate soreness of muscle. Currying helps the circulation of the blood and opens the pores by removing the scurf skin. The mane, foretop, and tail, must be thoroughly combed, and the feet examined and cleaned to see that no stones or dirt accumulate. A recently introduced horse-shoe is in this respect good—the ground surface of the shoe is beveled so as to favor the ejection of stones, mud, snow, ice, etc. (Fig. 13).

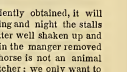

Fig. 13.

Bedding should be cut for horses as well as for other stock; they will sometimes prove troublesome by eating their bedding, in which case, if sawdust can be conveniently obtained, it will be the best litter for them. Morning and night the stalls should be cleaned out and the litter well shaken up and aired, and all the food remaining in the manger removed and replaced with fresh. The horse is not an animal that we want to fatten for the butcher; we only want to keep him in good working condition; if fed too much he will become "logy" and lazy. Breeding mares are usually at rest during the Winter. Their period of pregnancy is 11½ months, varying a few days as they grow older. They require about the same care as other horses during Winter, attention being paid to keep them from straining or jumping as the period for foaling draws near. They should not be used unless naturally very gentle. Colts should not be castrated during the Winter if it can possibly be avoided; from 4 to 12 months is the right age, and Spring is the best time.

POULTRY.

You can not winter poultry profitably without a building for the purpose; it may be a simple shanty or a build-

ing of tasteful architectural appearance. Before Winter sets in, this building should be whitewashed, and the floor covered with gravel; if you confine them to a yard the house must be kept whitewashed all the time. The principal care of poultry in Winter consists in preparation for market, and obtaining eggs—in the latter, few succeed. Shelter and warmth are the first requisites—then clean straw and whitewashed boxes for nests, and plenty of food. A supply of lime, ashes, gravel, corn, and *meat*, is necessary, and if these and plenty of *unfrozen* water be given, there need be little fear that eggs will not be plentiful in January. I seldom if ever give my fowls enough animal food during the Winter; in the Summer they scratch up worms and insects for themselves. To fatten chickens for market, confine in small coops, keep them quiet and feed on boiled corn or ground oats and milk—the secret is to feed often and but little at a time. If intended for a distant market they should be fasted for from twelve to fifteen hours before killing, or better yet, afterward filled with powdered charcoal. Judge Buel asserted that they may be kept for two months by pursuing the latter course.—Turkeys consume so much food during the winter that it will generally be found advantageous to dispose of them early. They may be all fatted together and killed, and then either filled with charcoal, as recommended for chickens, or frozen and kept so, this, however, some say affects the taste.

Having no acquaintance with the management of bees, I must, with these remarks, close this essay on the Winter management of farm stock, well aware that I have not done the subject justice; and I am sure few have sufficient knowledge of *all* the different animals to give perfect rules for the management of each. Each kind is a study to which alone a man may devote a lifetime. R.

For the American Agriculturist.

Too Much Fat.

MR. EDITOR.—The candle makers ought to pay some agricultural papers handsomely, and they could also well afford to *grease* a good many judges at Agricultural Fairs, for their efforts to make tallow and lard plenty. Thanks to the teachings and decisions of the above-mentioned authorities, the notion very largely prevails that the chief end of stock breeding and feeding is to make fat. Great stories are told of Mr. A's oxen which dressed ever so many thousand pounds, with an unheard-of amount of rough tallow. The public are invited to examine extra specimens of abundant tallow hanging in the stalls of the butcher who has paid premium prices for *the great fat steer*. When a farmer proposes to exhibit an animal at the Fair, he keeps a good path trod between the corn crib and the feeding place, and every ounce of fat he can crowd upon the creature's ribs, he counts as one more chance towards a favorable opinion of the judges. If pure fat were desirable food, all this would be highly commendable, but the fact is, comparatively few eat the unadulterated article, and most of it finds its way to the tallow-chandlers. A mixture of fat with the lean, is almost universally relished, and is not unwholesome; but an over-fed, enormously fat animal, such an one as attracts the gaping crowd, is not in a healthy condition, and can not furnish healthful food. It is the opinion of well informed men that many diseases arise from the excessive use of fat meat, particularly pork, which is common in this country. I believe it should be the aim of breeders to increase the quantity of meat upon an animal's bones, without striving to cover it with tallow or lard. An animal of vigorous constitution well fed—not stuffed—and properly exercised, will develop a large amount of muscle (good lean flesh), and by proper selection among such specimens for breeding purposes, this characteristic can be fixed in the progeny. JONATHAN.

AN ARTIFICIAL SOW.—The Mark Lane Express gives the following, from a correspondent: "A fine sow, having twelve sucking pigs, owned by a pork merchant in Monkwearmouth, died suddenly. The proprietor, who is an ingenious character, set to work and formed a rough model of a sow in wood, hollow in the center, and furnished with twelve teats formed of raw hide. The interior was filled with milk, and the young pigs took to it very naturally, and throve well!"

For the American Agriculturist.

How to get Good Crops.

Manure is the great secret of profitable farming. Skill and tillage are important in their places, but these avail very little without manure. With plenty of manure, we can get almost any thing we desire out of old land. Without it, we can hardly get pay for our labor.

To show the power of manure to produce crops and to make money, I will give the following statement of the treatment and produce of three quarters of an acre the past season.

The field was a worn out meadow, producing less than half a ton of hay to the acre, and had received no manure in twenty years, except from cattle pastured in it. The soil was a gravelly loam, and the subsoil a yellow loam of good quality. About thirty dollars' worth of manure was taken to the field during the winter, principally night soil and hog dung. This was spread and plowed in in the Spring. At planting time a compost was prepared of one hundred and fifty pounds Peruvian guano, a cord of muck, and a half cord of night soil, for dropping in the hill. This was mixed three weeks before planting, and put in a pile under cover.

The lot was plowed about seven inches deep, and harrowed, and planted April 15th, with Wendell's Seedling potatoes, putting a handful of the compost in the hill. They came up in about three weeks, and as soon as the ground began to crack with the young shoots, the whole piece was run over with a light horse harrow, destroying every weed. This was equivalent to once hoeing, and gave the crop a good start. About the middle of June, the spaces between the rows were planted with beans, cabbages, and sweet corn for a succession crop. The potatoes were dug from the first to the twentieth of July, when the succession crops had the field. The cabbages were nearly a failure, owing to depredations of worms, the last of July. As the corn began to give ears the last of August, the spaces between the rows were sown with white turnips—cowhorn, strap leaf, and other varieties.

The receipts were 84 bushels potatoes—Sold at from 80 cents to $1.20 a bushel, averaging $1....	$84.00
Beans and Cabbages.....	2.00
Sweet corn sold at 10 cents a dozen.....	20.00
Rock turnips, 30 bushels—sold at 32½ cents.....	13.00
White turnips, 20 bushels—sold at 20 cents.....	4.00
White turnips, 50 bushels, for feeding, at 10 cents..	5.00
Total from three-fourths of an acre	$128.00
The expenses of the crop were—Rent, $10.00	
Manure 40.00	
Labor..... 25.00	
	$75.00

This shows a profit of $53 on three quarters of an acre of land. If we reckon one half of the manure only as expended upon the crop, as is common, it will make twenty dollars more added to the crop this year. There can be no doubt that the land is in much better condition than before it was broken up. This statement is not given as an example of large productiveness, or extraordinary profit for market gardeners who have the conveniences for forcing and more abundant manuring. But it shows what may be done by farmers in the vicinity of good markets, by a little extra pains. Early potatoes, early planting, and high manuring, will make at least a difference of three weeks in getting potatoes to market, and this adds about one half to the price. Potatoes that go quick at one dollar and a half a bushel July 4th, are worth but seventy five cents a month later. A great many acres conveniently situated to market, might be easily made to double their productiveness and their profits. PRACTICAL.

Ice for Use and Ice for Sale.

The ice crop is every year becoming more important—no longer regarded as an article of luxury and an accompaniment of sumptuous living, but a necessity of life and trade. To our milkmen and butchers, in public and many private houses, especially in hospitals and sick rooms, it is *daily bread*. Our navy consumes immense quantities of ice also, and just so far as our commerce is re-established in the South, will the demand increase, while we at the North are annually increasing the home consumption of the article, in a ratio which often more than realizes the expectations of those upon whom the public depend for a supply. Should a general opening of trade with the South not occur until late in the Spring or Summer, the demand for ice at large prices will be very great, and the price at points on the coast favorable for shipping will be greatly increased, unless a large supply is stored this Winter to meet this very emergency.

Ice, to keep well, must be stored on dry ground, and protected from the sun, from rain, and from a circulation of air. The smaller the mass of ice the more thoroughly must these conditions be met. A house twelve feet square, double boarded, with a space of 10 or 12 inches filled with sawdust between the boardings, well roofed, and shaded from the mid-day sun, and situated on dry ground, and well drained, will keep ice well enough for a family, though the waste will be considerable. When ice is packed very closely and in very *large* quantities, a thatching of straw and hemlock boughs will be relatively quite as effective. The use of boards or rails to keep this protection in place, will be found advantageous, and it should be so disposed that rain will be completely shed; and all water, whether from rain, thawing of the ice, or other sources, must be carried away in surface drains around the outside.

Places Wanted on Farms for Boys.

Scarcely a day passes without inquiries addressed to the Office of the *American Agriculturist*, in person or by letter, from business men who wish to place their sons upon farms with good intelligent cultivators, where they may learn both the theory and practice of farming. Many of these business men are able to purchase farms for their sons, but wish first to give them a preparation. A majority of them are willing to pay liberally for board, and oversight. Others desire their sons to work nearly or quite enough to pay their board. Now we think it would be for the mutual advantage of all concerned, if a considerable numbers of farmers of the right class, would take these boys; few of them are unruly, but most, quite the contrary. We will take it as a favor if any of our readers who know of good locations for boys on farms under good cultivation, where they could be taken into the family, will let us know the name and address of the farmers to whom application can be made. Such letters we will place on file to be referred to by those who may hereafter make inquries of the character referred to.

French and German Asters.

The engraving presented herewith exhibits, so far as can be done in black and white, the appearance of a beautiful bouquet of Aster Flowers shown at the *Agriculturist* office recently, by John Wesley Jones, of Columbia Co., N. Y. One can hardly have an idea of the real beauty of these flowers, without seeing the blooms themselves, or a *colored* picture of them, showing the brilliant crimson, purple, blue, etc., with the intermediate colors. For the purpose of raising seed for distribution to our subscribers, we sowed nearly ¼ acre with these *improved* asters, and never have we seen anything more beautiful in the floral line.—Perhaps no flower has undergone more changes and improvements within a brief period, then the aster. The single ray of "red, white, or blue," has given place to the full quilled, Giant Emperor, Chrysanthemum flowered, Ranunculus or button formed, Pæony perfection, etc., with every shade of color, running from pure white to lilac, pink, and crimson; and from light lavender to deep blue, with the various shades intermingled in the same flower. Then in size, they range from the dwarf ranunculus-flowered, scarcely three-fourths of an inch in diameter, and growing on a stalk less than one foot high, to the giant sorts on three to four-feet stalks, with flowers two to three inches or more in diameter, and resembling the pæony in form and size, but greatly excelling it in beauty of petals. These great changes have been brought about by carefully selecting seeds of the finest blooms, and giving them high culture, so as to change the *stamens* into *petals*. French and German florists, conspicuous among whom is M. Truffaut, have brought about these "improvements," and made this one of the most desirable flowers. Besides being one of the prettiest annuals, the aster is of very easy culture. It will flourish in any good garden soil, and may be sown in the open ground at any time in May, or June even, covering with one-fourth inch of finely pulverized soil. They are best sown in drills, 15 inches apart, or thinly massed in small plots, with the tallest sorts in the center. When practicable, it is desirable to sow a portion of the seeds in pots, under glass, early in April, or the last of March, and then transplant them into the open ground, in the border and elsewhere, when the ground is warm, and the weather settled. These, with seed sown in the open ground in May and June, will furnish a succession of beautiful blooms all through the Summer and Autumn, until severe frost cuts them down. It is unfortunate that the finest blooms supply so little seed for wide diffusion. The petals or flower leaves in the most double sorts nearly or quite fill up the center, leaving little space for seed.

Nos. 1 and 5, Chrysanthemum Asters.
Nos. 3 and 4, Globe Quilled Asters.

Nos. 2, 7, 9, and 10, Truffaut Pæony Asters.

A BOUQUET OF FRENCH AND GERMAN ASTERS.

Drawn and Engraved from the Flowers, as shown at the Office of the American Agriculturist, November, 1861.

Use of the Pruning Knife during Winter.

Mild weather in Winter is the pleasantest time for pruning, because we then have more leisure and can work more deliberately, because we can see every part of the tree, and because there is nothing on the ground to be injured by the feet, or by the falling branches, or their removal to the wood pile. It is the experience of every body who has pruned ornamental trees, and especially apple trees much, that sometimes the scars will heal, and sometimes they will not—the wood often becoming soft, and penetrated by decay, and finally, seriously injuring the tree. It will be found that a limb less than two inches in diameter will seldom make any trouble in this way. Large limbs cut in the Winter, and particularly toward Spring, will bleed, often profusely, so soon as the sap starts. The sap in early Spring is very fluid, and has the property of "scalding," that is, killing the live bark upon which it flows in any considerable quantity. Thus we often see where a large limb has been cut off, a decayed hole and a strip of dead bark or bare wood for a yard or more beneath. After the leaves put out in the Spring, the sap becomes thickened and sluggish in its motion, so that when the first evaporation takes place on the fresh cut surface, none will flow out, while the wood itself remains hard and impervious to water, and the scar, however large, gradually heals over. On the whole, therefore, we advise never to cut off large limbs except after blooming time, though these may be partly lopped off, and reduced in size in Winter, so as to be conveniently removed altogether in May or June. To debar oneself the privilege of doing any winter pruning is, we find, to crowd work terribly in Spring, and to make this otherwise pleasant labor a trial and a bugbear.

Pruning Grape Vines, and letting them Grow "Naturally."

A friend asks if the whole system of pruning the vine is not unnatural and mischievous? It *is* unnatural, but it is equally unnatural to raise such fine fruit as we do by this means; and you will not therefore object to the fruit, we imagine. If you insist on natural vines and natural fruit, go into the woods, and climb the trees for the small, sour, hard clusters. And if you don't come home feeling somewhat unnatural in the stomach, we will yield the point.

To get large and handsome fruit, we enrich the soil; but this also induces an overgrowth of canes, which must be checked by pruning; and to restrain this overgrowth most effectually, we must of necessity prune some in Summer.

Our friend admits that there is some sense in Summer pruning, "for that sends all the strength of the vine (he says) into the clusters, and lets in the rays of the sun upon the fruit."

But are you not a little too fast here? How does cutting off the foliage send the strength of the vine into the fruit? It is an accepted fact, that the clusters get their growth and flavor through the action of the foliage. As well take away a man's stomach and lungs, that so he might get strength! And as to letting in the sun on the clusters—why does Nature take such pains always to cover up the clusters? Have you not observed that the fruit ripens in the shade of the foliage just as quick as when exposed? If you wish to make your berries small, and sour, and to keep them from ripening, then strip the vines of their leaves almost entirely. If you wish them to be large and to ripen early, then give the vines a moderate Summer pruning, consisting chiefly in rubbing out all superfluous shoots as soon as they appear, and in pinching off the fruit-bearing branches three or four eyes beyond the last cluster.

Daphne Cneorum.

This is a beautiful little *evergreen* plant, growing about one foot high, and forming a dense mass of foliage, which is covered the greater part of the Summer with small purple flowers, that give forth the most delightful fragrance. It is perfectly hardy, withstanding our coldest Winters without injury. If there is any one plant better deserving a place in the garden than another, it is this beautiful Daphne. It will grow in almost any good garden soil; but one composed partly of leaf mold is the most suitable. It is easily transplanted while young, but the old plants are very impatient of removal. It is propagated by layers, which should be put down in the early part of the Summer, or like other evergreen plants, at the time it is making the most rapid growth. The best mode of making the layers is shown on page 131 of the May *Agriculturist* for 1860. The plants have been somewhat scarce, but nurserymen are turning attention to their propagation, and they will ere long become abundant, and we shall hope for their wider diffusion. The poor mountaineers of Tyrol and Switzerland bring large quantities of this plant to the villages, and sell it in little nosegays, under the German name of Stein Rœslein, (rock rose).

No Glut in the Fruit Market.

Some fifteen years or so ago, the prediction was continually made that, in ten years' time, there would be a glut in the fruit market. Nurserymen were advised to wind up their affairs and get out of the business in time, or they would soon have no customers for trees. Farmers were counseled to refrain from planting orchards, for it was predicted that even choice fruit would not sell at good prices. There was then quite a little panic, here and there.

But how has the event proved? Trees have continued to be planted from that day to this, and they are all wanted. Many have died from the neglect and carelessness of orchardists, and from the vicissitudes of the seasons. The market for fruit has continued to enlarge. There are millions of mouths to be filled now, where, twenty years ago, there were thousands, and more people appreciate choice fruit. They have found out that it is healthy food, and that it is cheaper to pay the apple-man's bill, than the medicine-man's. Then, too, the foreign market has been brought to our very door, within the past fifteen years; it is now only eight or ten days off, with an unlimited demand. It rarely happens that apples, our most common Summer fruit, are so cheap that even every well-to do family can afford to use them with entire freedom. Abundance in one locality usually counterbalances scarcity somewhere else, and prices are generally maintained.

The market glutted? Send on your fruit! Plant orchards, and take care of them. Raise fruit in variety, early and late. If you are within easy reach of a city market, raise the smaller fruits, strawberries, currants, raspberries, grapes, cherries, peaches, etc. Before the market begins to be glutted, we promise to raise the alarm.

Cactus Speciosissimus.

The above cut, though correct in outline, gives but a poor representation of this most gorgeous of all this most beautiful tribe. The expanded flowers of well grown specimens are from 7 to 8 inches in diameter, and of the most brilliant blending of scarlet, crimson, and violet shades. We have frequently seen plants of six feet in hight, and three feet across, with 30 expanded flowers at a time, and thus seen, it equals in beauty any production of the floral kingdom.

Another interesting species of the genus is *Cactus grandiflorus*, or more correctly, *Cereus grandiflorus*, having flowers considerably larger than the above, of a whitish yellow, which are expanded only at night—generally in perfection at midnight—emitting a most delightful fragrance. This variety is not quite so free to bloom as *speciosissimus*, and this, coupled with its rare habit of expanding its bloom only at night, makes it, when in bloom, an object of more than common interest. These species of *Cactus*, though natives of the tropics, are of easy culture. Pieces of the stems take root readily in the open ground during the summer months, in any place where the soil is loose and sandy, and never for any length of time saturated with water. When rooted, they may be potted in sandy loam well enriched with rotted manure, and removed to the plant room or green-house, where they should never be exposed to a temperature of less than 40°, nor much above 80°. The temperature of what is termed a "warm" green-house, is best suited to develop their growth and bloom. It is a common belief that the cactus requires little or no water: this is a mistake, though they will exist for months without water, yet in this state they do not grow. If it be desired to keep them growing, in a temperature say of 60°, they will require water *when dry*, the same as any other plant. In a low temperature, with a damp atmosphere, watering must never be given, as in that condition they will never become dry.

Jottings in the Flower Garden.

Not made this Winter with mittens on, but in Summer and Autumn, and now transcribed at leisure for the readers of the *Agriculturist*.

July 10th....These Japan lilies are not doing as well this year, as formerly. An old florist tells me that they need a peculiar soil, and a change of soil once in three or four years. They grow best in a mixture of sand, wood's earth, a little old manure, and common soil. They *are* well worth all the care they require.

July 15th....This patriotic assortment of verbenas works pretty well. In former years, I had set out my plants without much regard to arrangement of colors, aiming only to get the finest flowers in the market. But this year, I determined to try something new; and the "Red, White and Blue" being the national war-song, I thought I would inscribe it on my verbena bed. So here in front, is a curved line of red, one of white next behind, and one of blue beyond. Aside from the patriotism of the thing, the colors are such as always sort well in a bouquet. Don't tell me that this floral flag will not help decide the fate of the nation!

Aug. 20th....Hail to the new Gladioli! What an improvement on the old sorts! The long honored *floribundus*, and *gandavensis*, and *byzantium* were well enough in their way, and are not to be cast aside now, but these new French hybrids eclipse them. Let's see; it was M. Souchet, of Paris, who orighated most of these novelties. Great praise to you, sir!

Here, mark down the names of a few of the best in our border. They are, Brenchlyensis, Galathee, Madame Henrieq, Osiris, Joan of Arc, Egeric, Adonis, Hebe and others. Some of these, like Joan of Arc, are very tall and need stout rods four feet long to support them; otherwise they will be blown over and broken. It is one excellence of these plants that they require so little care. Any good garden soil will answer; and they need no watering or muleling or guarding from insects. Set out the bulbs a foot apart, about the 10th of May, drive in stakes by the side of each, and tie up the stalk as it grows, with cords. In the Fall, before the ground freezes, cut off the stalks near the ground, dig up the bulbs, and keep them in a dry root cellar, free from frost.

Sept. 3d....Take off your hat to this bed of plants whose leaves are their flowers, as Patrick says. Don't know their names? Well let us read the labels on them. Here is *Parfaitum grande*, with broad, leathery leaves of a green ground mottled with yellow spots. An odd thing. The next is a new variety of *Amaranthus tricolor*, and so is that. The first, with dark, purplish crimson leaves, dashed with blotches of bright vermilion, is very striking, when the sun falls upon it. And that, with pale green leaves, strongly marked with dark crimson and yellow at the base, is quite curious and showy. Next to these, are plants of the "Dusty Miller Geranium," whose silvery leaves are in striking contrast with the foliage around, and especially with that of *Perilla Nankinensis* beyond. As a fringe to the whole bed, here is a row of silver edged geraniums.

This border has, on the whole, proved the most noticeable corner of our flower garden, this Summer. The vivid contrasts of color and form of foliage, and the fact that the colors are part and parcel of the leaves, not of the flowers, is what arrests the attention of man, woman and child. Usually the leaves of a plant have to play second fiddle, but here the blossoms have to do that, and the *leaves* make all the show and have all the glory. We fancy that the Petunias and Lilies yonder are jealous of this much admired bed, and would fain pull themselves out at the root, in their passion to get across the walk and thrash these showy leaves!

Sept. 10th....These double Zinnias have not turned out to be so grand an affair as was predicted. In the first place, full two thirds of the costly seed is spurious, and then the double flowers are less brilliant than the old, single sorts. Still, they are valuable for a variety.

Near this bed, is a root or two of the Sensitive Plant. Will children and young ladies ever tire of noticing this curious plant, and touching its acacia-like leaves, to see them shrink, close up, and droop to the earth! It would take away much of the poetry of the thing, if I should tell them that the plant is just as sensitive to the touch of a stick as to that of the human hand; so I won't tell them. But even with the poetry taken out, it is a curiosity in vegetable life. *

Much from Little—A Mechanic's Homestead.

Within a mile from where we now write, there lives a poor man, who has accomplished so much in his little garden, that we must speak of it as an example to others. About ten years ago, when he came into possession of his acre and a quarter lot, a small house and barn stood upon it; there were three old apple trees in one corner, and hard by were two scraggy knot-covered plum-trees: on each side of the front door were two Balsam firs. A part of the ground was devoted by the former owner to potatoes and a few other vegetables. Such were the "investments" on this place.

The new occupant on taking possession early in the Spring, began with the apple-trees, which bore nothing but worthless "natural" fruit. He grafted a part of each tree with R. I. Greenings, Baldwins and Spitzenbergs, and at the same time scraped the trunks and limbs clean of vermin nests, and gave them a good caustic washing. The half-dead plum-trees were cut up by the roots and burned, and their place made good by several nice dwarf-pear trees. The Balsam firs were not disturbed, but a few other handsome shade trees were set out in front of the house to keep them company. The whole of the ground, except a narrow grass plot around the house, was put under the plow, then dragged and worked smooth for planting. Potatoes and corn were, of course, the main crops, but not the only ones. Beets, onions, carrots, cabbages, turnips, cucumbers, squashes, pumpkins, beans, peas, and all the rest had their allotted place. Most of these articles were grown in drills, Mr. Johnson believing this saved time, labor, and space.

Our friend is quite systematic. On the south and west sides of his garden, where the ground was somewhat shaded by fences, he set his raspberries and currants, believing that they would thrive better there than in a very sunny exposure. But he did not fall into the mistake of allowing weeds to creep in from a neighbor's land. The raspberry plants were annually manured and kept under as clean cultivation as any other part of the garden. On the north side, protected from the cold by a high fence, he set his grapes. He set others, too, on the sunny side of his shed and barn, occupying every available spot with a choice variety. At first he planted only the Isabella, Clinton, and Catawba; but of late, he has added the Diana, Rebecca, Concord and Delaware.

Dwarf pears have succeeded well in his hands. Having two or three cross-walks, with borders on each side, he set out pears in these borders eight feet apart. He planted only those sorts which had proved generally hardy and productive; and rigidly confining himself to these, he has met with few failures. He used no manure at the time of planting—for he was too poor to buy it—but he has enriched the surface around them every year since.

And this suggests another thing. His land has been brought up from comparative barrenness to high fertility, without purchasing a single load of manure. The droppings of the cow have been carefully saved and mixed with absorbents. The pig-pen and hen-roost have been little mines of wealth. Weeds and other refuse have been thrown in for the grunters to work over into compost. In one corner of the little barn-yard, a saucer-shaped place was dug out water-tight and capacious. Here, muck, sods, saw-dust, chip-dirt, leaves, and old straw were thrown from time to time, to absorb the kitchen and chamber slops. Nothing was allowed to waste on the premises, that could be turned into manure. Thus at the end of every year a fine pile of rich compost was provided, ample for all the wants of the place.

Mr. Johnson is a mechanic, and has been obliged to take care of his place entirely out of the regular business hours. He hires no help, but is aided by the nimble fingers of two sons to do much of the light work. As already intimated, ten years have wrought a great change in his place. The apple-trees furnish him all the fruit he needs in Winter. He has pears, grapes, and berries, not only enough for his own use, but some for market. Within the last two years, his daughters have prevailed upon him to lay out a little wider space around the house to grass, and this they keep neatly cut and swept. They have also got a few flower beds, and trellises for vines; so that now, this is one of the most attractive cottages in the neighborhood.

A Hint in Grape Culture.

We noticed last September, in the grounds of a friend who is largely interested in grape-growing, that his Isabellas standing on level ground had not begun to color, while on one vine standing on a bank or terrace, the berries were ripening up finely. What means this? we asked our friend. He could only explain it by saying that originally this vine was as low as the others, and then matured its crop no earlier. But within the past two years, the ground had been graded and cut away near it, leaving this vine high and dry above the others, and since then it had become an earlier grape.

This afforded a good illustration of what we have often enjoined, viz.: the importance of drainage for grape growing, and we put it on record here for the benefit of others. Now, every man can not plant his vines on banks or terraces, but he can see to it that the subsoil of his vineyard has no standing water in it. In choosing a place for planting a grape, or a lot of grapes, by all means select a dry spot with a sunny, open aspect. And if there is any doubt about the dryness of the subsoil or if a wet soil must be used, give it a thorough draining. Free circulation of air, if the vine be sheltered, greatly promotes the ripening of early fruit.

Propagating Plants from Cuttings—Valuable Suggestions.

[This subject is daily becoming of more importance to all classes. A large number of plants are best propagated from slips or cuttings, while many improved varieties can only thus be propagated in purity. Every person who grows a tree or shrub, should understand, if he do not practice propagation.—At a recent conversational meeting of the Brooklyn Horticultural Society this subject was discussed at length. The remarks of Mr. A. S. FULLER were so valuable, and of such general application, that we requested a transcript of them for the *Agriculturist*. Mr. Fuller held, that to enlighten the general public on the processes of good nurserymen, as well as the "tricks" of dishonest ones, would, in the end, benefit reliable dealers, by preparing purchasers to appreciate well grown plants. We omit, for want of room, the first portion of the remarks.—ED.]

In propagating plants from cuttings we should bear in mind that there are other desirable objects besides the one of increasing the number. One of the most important is, to increase the vigor of the plant so that it shall produce better fruit or flowers, if possible, than its parent. This can only be done by a proper selection of the cutting, and a continued watchfulness from the start, never allowing the plant to become stunted at any period of its growth. One of the conditions of success is a proper selection and preparation of the soil; one of a sandy nature, moderately rich, is, perhaps, the best adapted for almost every description of cuttings. Where the soil is tenacious, sand should be applied in quantities sufficient to make it porous enough to allow the water to pass through it readily. And further, the soil should be pulverized at least eighteen inches deep;—not that a great variety of plants will not grow from cuttings without doing this, but they will succeed better if the soil is thoroughly and deeply manipulated.

Instead of mulching the cutting during the Summer for the purpose of keeping the soil moist, as sometimes recommended, we prefer stirring the surface of the soil with hoe or rake, at least once a week, or oftener if possible. This allows the air to penetrate the soil, carrying with it the moisture which is always present. From the many experiments which we have tried, we have uniformly met with better success when this plan was followed than when any kind of mulching was used.

The best time to make cuttings is in the Fall as soon as the wood is ripened. At this time a portion of the sap is in a semi-liquid state, and is descending, solidifying as it passes along, and depositing the last layer of woody fiber of the season. When a cutting, is properly treated, this woody fiber or alburnum slowly grows from the end of the cutting, and forms the callus, which in its turn changes to roots. If the cuttings are not taken off until they have been exposed to severe cold, all the alburnum has become hardened fiber, and then it becomes necessary for us to place the cuttings in a position where warmth and moisture will again partially liquify this before a callosity will form. As it takes more or less time, according to circumstances, for it to change a portion of its structure so as to form roots, it is better to give it plenty of time than force it, as we sometimes do.

There is another advantage in making cuttings in the Fall, which is, that we can have them rooted by the time vegetation starts in the Spring. It is a well known fact that roots will form at a much lower degree of temperature than leaves, therefore if cuttings are placed in the ground in the Fall, and its temperature kept a little above the freezing point, roots will be produced while the leaves will remain dormant. When the rise of the temperature commences in the Spring, these cuttings throw out roots (if they have not already done so) more readily than if but recently made; for the change has been gradually going on in transforming branches to roots, although to the eye it may not be apparent. Again, plants that are exposed to severe cold, lose much of their vitality, and, as before stated, the alburnum from which the roots spring becomes so hard that it emits roots very slowly, if at all; and sometimes we are compelled to put the cuttings for a time in water, as is often done with grape cuttings. This softens the alburnum again, which is necessary to form roots.

Sometimes it is not convenient to plant cuttings in the Fall, as the soil may not be prepared; in that case they may be tied up in small bundles and buried in the earth—either in the cellar or in some dry place in the garden. But it is better, as a general thing, to plant them in the Fall, and then cover sufficiently to keep out the frost, as with some varieties, like the quince, which emits roots from every portion of the bark, it is much better to place them where the soil can come in contact with every portion of the surface, thereby softening the outer bark and allowing the roots to protrude. With those varieties of plants which emit roots mostly from the severed part—or at the buds, it will make little difference whether the whole surface comes in contact with the soil during Winter, or only the lower ends; the latter will be the ease, if carefully buried in bundles.

The first cuttings made in the Fall are generally from the currant, as it ripens its wood, in this latitude, by the middle of September; and as soon as ripe, the cuttings should be made. Take good, strong wood of the present season, and make the cuttings about six inches long, cutting them off smooth just at the base of a bud, square across. If you wish to prevent them from throwing up sprouts from under ground, cut out every eye or bud, excepting two or three at the upper end. Now draw a line across the bed which is to receive the cuttings, place the back of the spade to the line, press it into the soil nearly perpendicularly to the depth of six inches, and throw out the soil, making a trench in the shape of the letter V. Set the cuttings two inches apart along in this trench, with the upper end even with the surface, as the soil will settle enough during the Winter to expose the upper buds; put in a little soil, say enough to cover the base of the cutting one inch; then with the handle of the spade or a piece of plank press the soil firmly down to the base of the cuttings. The object of this is to exclude the air from the recently severed part and furnish it with a supply of moisture. Not that the cutting takes up any considerable quantity of water, yet it is necessary that this portion of the cutting should not become dry, for then a vacuum occurs, which will be filled with water and cause it to decay. Currant cuttings planted early often become rooted by the time Winter sets in, without making any leaves; and they will make twice as much growth the next season as they will if their planting is deferred until Spring.

Cuttings can be made of most kinds of shrubberry as soon as the wood is ripened and the leaves can be taken off without injury to the buds adjacent, and planted in the same manner as described for currants. Gooseberries may also be treated in the same way.

All the varieties of syringa, althea, Wiegelia, deutzia, viburnum or snowball, Forsythia, honeysuckle, spiræa, climbing, Bourbon, and hybrid perpetual roses grow readily, if cut before frozen.

In growing quinces from cuttings, one, two or three year old wood may be used; and we have found it extremely advantageous to pack the soil very firmly about the base of the cuttings, leaving it loose below the cutting and at the surface. Having grown many hundred thousands, we have always found our success (other things being equal) just in proportion to the care taken in making the soil firm about the base of the cuttings. Merely sticking them down, as is sometimes done, depending upon the rain to settle the soil, generally proves a total failure.

The method ordinarily pursued in making grape-cuttings, is to cut them into lengths of from one to two feet; but we think the short cuttings are preferable. We make them about six inches long, or with only two buds. But sometimes the buds are further apart, and in that case we have to make the cutting long enough to include the two buds if no more. If the buds are so near together that two will not give us a cutting four to six inches long, then make them with more than two. The cuttings should be made as soon as the wood is ripe, and either planted immediately or "heeled in" in some dry place in the garden or cellar. They should be planted at least six inches apart in the row, and the rows one to two feet apart. Set them perpendicular, leaving the upper bud even with, or a little below the surface; press the soil firmly about them, and attend to hoeing and keeping the soil loose between the rows during the Summer. Some varieties grow more readily from cuttings than others, but we have tried none of which a greater part will not grow if they receive proper attention.

There are some kinds of hardy plants and trees—like the Paulownia among trees, and the double flowering almond shrubs, and the raspberry and blackberry among small fruits—that do not grow from cuttings of the ripe wood, yet can be multiplied with great rapidity from pieces of the *roots* planted in any good rich garden soil.

Among the many theories advanced to explain why these variations occur, none are entirely satisfactory. Much practice becomes experience, and this is our only guide to success.

Wire Worms.

These pests, terribly severe on some land, and quite unknown on others, baffle the efforts of the most ingenious to work their destruction. They abound in light, moist land, in which inert vegetable matter is found, and attack, as most of us know by experience, roots of grass, grain, turnips, potatoes, etc., in all ages and conditions. The worm is the pupa of a small beetle, and lives, it is said, for *five years*, ever committing its depredations before it arrives at maturity, and assumes the form of the perfect insect. A writer in the "Scottish Farmer" makes the following interesting statement: "The late Mr. Pusey found that rape-cake had the effect of destroying large numbers of wire worms. He caused it to be broken into pieces of the size of beans, and to be sown over the land. The insects eat their way into the pieces of rape-cake, and whether from dying the death of gluttons, or being destroyed by its other qualities, he found numbers of dead wire worms imbedded in it." Rape-cake is an excellent manure, and may be applied at the rate of 5 to 7 cwt. per acre. This writer also recommends Peruvian guano applied in the Spring, alone or mixed with rape-cake, as a preventive, and esteems it of especial virtue, sowed with the seed of turnips and similar crops. The experiment may well be made to see if cotton-seed oil-cake will not answer the same purpose as rape-cake, which is difficult to obtain in this country.

Chamberlains's Mode of Growing Fruits and Plants in Baskets of Moss.

Considerable attention is being attracted to the experiments of Mr. Chamberlain, who proposes to grow not only ornamental plants, but even fruitful vines and trees, in baskets filled with moss and a small quantity of artificial soil. The engraving above is an exact representation of a basket of growing grapes recently presented to the lady of the Presidential Mansion, at Washington. The basket is about 30 inches across at the top. At a meeting of the Brooklyn Horticultural Society there was shown a peach tree in a 9-inch basket where it produced ten beautiful peaches; a grape vine with a dozen well formed clusters of good flavored fruit; strawberries in full bearing, as luxuriant as if in the open air; ripe pineapples, etc. At Mr. Miller's, 29 Broadway, may now be seen a variety of ornamental plants, with pineapples, strawberries, etc., all growing in baskets.—The main features of the process are: a plentiful supply of moss around and above the roots to retain moisture, and a comparatively small quantity of artificially prepared soil—consisting mainly, we believe, of powdered charcoal and ground bones. A patent has been taken out for portions of the process, which will somewhat interfere with its general introduction, though we presume Mr. C. will find it to his own interest to facilitate a wide adoption of this pleasing, if not practically useful mode of growing dwarf fruit trees, vines, and all kinds of ornamental plants.

A Sixty Dollar Green-House.

The articles on "Green-Houses for the People," published in last volume, have awakened a good deal of interest among many who have a taste for these structures, but who have hitherto supposed that the most limited greenhouse would cost $500 to $1000. We have many letters asking the lowest cost of the cheapest building that can be got up to answer the purpose. Well, just to demonstrate that green-houses are within the reach of a large class, we are now putting one up, which will be, in outside dimensions: 32 feet long, 12 feet wide, 9 feet high on one side, and 4 feet on the other, covered with 12 sashes, each 3½ by 6 feet. The work is mainly done at odd spells by two men, for whom we have little else to do at this season, so that their time is not reckoned. The outside expenses for materials, etc., we estimate at only about *sixty* dollars! We intended to give a full description and account of expenses, next month, but that will be too late for many inquirers, who wish to get up something similar, during this leisure month of January. So here is a brief description. (Fig. 1 is a skeleton, to show the construction of the parts—the posts, portions of the plates, rafters, siding, etc.)

First, a lot of refuse oak and chestnut logs were cut up into various lengths, and split into quarters. They were hewn somewhat straight on two sides, one side being made pretty true. These are set up in the ground firmly, like fence-posts. Seven on the rear or north side rise 9 feet above the ground, and seven others on the front or south side rise nearly 4 feet. The two posts on each end are of a hight to line with corner posts. These rough posts, set with the straight sides out, are furred out on the inner sides, by nailing on perpendicular strips, so as to make the thickness of the posts uniform, (about 10 inches), and also to give straight edges for boards. Matched boards are then nailed upon the outside and inside of the posts, except at *d*, which is left for a door. The boards are hemlock, 1 inch thick, 9 inches wide, 13 feet long, matched, and planed on one side. Thus planed and matched they cost 16 cents. each, delivered. The space between the outer and inner covering boards is filled with fine shavings, packed down. Charcoal, or saw-dust, or straw would answer, but we have chosen the shavings, because they cost next to nothing at the planing mill or joiner's shop. (Fig. 2 is a section of one side, showing two posts, with the manner of putting on the boards, and filling in the shavings, *before* putting on the plates.)

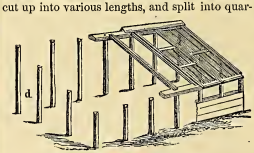

Fig. 1—SKELETON GREEN-HOUSE.

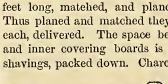

Fig. 2—SECTION OF WALL.

The tops of all the posts are sawed off true, and two plates laid upon the front and rear rows, and spiked down. Seven rafters are next laid on. These are 12½ feet long, and are cut in the form shown in the last September *Agriculturist*, fig. 3, page 273. This leaves places for six long sashes. We have each of the 12-feet sashes made in two parts, 6 feet long, and 3½ feet wide, the upper one to lap upon the lower one. The sashes are to be well made, and the whole (12) are contracted for at $33, including the glass well put in. The upper tier will be movable, and be held in place by cords, pulleys, and weights. A door hung at *d*, will complete the structure. The sashes are like Fig. 3, Sept. *Agriculturist*. These, and the boards and nails, are the chief outlay. As near as we can figure now, the cost of boards, plates, rafters, nails, and a coat of paint on the outside, will be about $25 to $27, making, with the $33 for 12 sashes, a total of about $60. (The items are: 90 boards, 16c. each = $14.40; 2 plates, 32 feet long, 3x10 inches, $1.37; 7 rafters, 3x4 inches, $1; door $1.75; hinges, latch, etc., $1; nails and spikes, $1; cord and pulleys, $1; painting, $3.50; sundries, $1 to $2.) Of course, if the labor was all hired, or we had other profitable work for our men, the cost would be somewhat greater. Many men, mechanics at least, can do all the work themselves. In the green-house here described, we shall, for heating only, use a common stove, and drain pipes, as described in November last, page 340. We hope these hints, taken in connection with what has been said in the last four numbers of the *Agriculturist*, will enable many of our readers to build themselves cheap green-houses, where more costly ones can not be afforded. We should have added, that the sashes we are providing, are just of suitable size and form to use on common cold frames and hot-beds, or on a small span-roof green-house, and they can thus be used for either purpose, when not needed for this green-house. Our cheap green-house can be examined by any one after the middle of January, when it will be finished and put to use. The inside measure will be 10 by 20 feet, giving an area or ground space of 200 square feet, and affording room for starting and growing many plants.

The Cheapest Fruit Gatherer Yet.

Recently a subscriber, N. G. Carnes, Riverdale, N. Y., brought to the office of the *Agriculturist* the cheapest fruit gatherer we have yet seen.

It is simply a narrow sheet of strong tin, bent to a circle, and the ends tacked to the end of a pole. The upper edge is cut with notches to pick the fruit, and a bag large enough to hold half a dozen or more fair-sized apples, is attached to the lower edge. The engraving represents the handle inserted in a tin tube which is soldered to the side of the apparatus, but this is not necessary. Any one can fit up this arrangement with a piece of old tin leader, a small strip of muslin, and a pole, at an expense of not over six cents, and it will be as effective as many implements of the sort costing ten or twenty times the amount. At least we judge so from the handling of the apparatus. The teeth or scolloped edges should be rounded, and filed smooth, to prevent their cutting the apples, pears, and peaches in careless handling.

THE HOUSEHOLD.

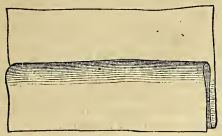

Fig. 1.

Impromptu Handkerchief Night-Cap.

Night-caps should be worn when sleeping in a draft of air, but not otherwise. A very good and effective head covering may be made in *half a minute* by any person obliged to sit or sleep in a draft of air in a room, or while traveling in cars, or elsewhere, if he have a fair size pocket handkerchief, or piece of cloth. *First*—Spread it flat and fold as shown in fig. 1; that is,

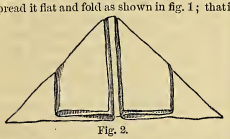

Fig. 2.

bring two edges together and then turn one edge back even with the fold. *Second*—Seize the folded part in the two hands, and turn the handkerchief directly over from you. Then bring the two upper corners over towards you as seen in fig. 2.

Fig. 3.

Third—Commencing at the side next to you, roll up the edge, as in fig. 3, so as to bring in and fasten the two ends of the fold. *Fourth*—Raise the hands up, and a bagging portion will drop down, which is to be placed over the forehead. Bring the rolled part back over the head and around the neck, tying under the chin, as seen in fig. 4.—Our artist seems to have caught sight of one of the "Zouave" soldiers in the Park Barracks, while making the sketch. Or more probably he wished especially to attract the attention of soldiers, for they of all others will find this a most convenient arrangement.—N. B. The *Agriculturist* claims no patent on this night-cap—it is free to all the world, and to the "rest of mankind."

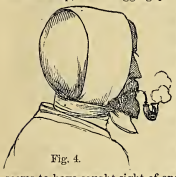

Fig. 4.

Knitting Mittens with one Finger.

The direction for knitting socks published in the December *Agriculturist* are proving of great interest and value. We already hear of knitting circles started in various parts of the country, originated wholly from seeing our article and illustration. One subscriber informs us that he saw over thirty ladies at work knitting socks the other evening, with the *Agriculturist* before them as a guide. We are glad to hear thus much, and therefore take the more pleasure in now presenting directions for knitting MITTENS. Gloves, though convenient for working and driving, are very cold, as the fingers, when kept isolated, do not help keep each other warm. Still it is quite essential to have the free use of one finger in almost all kinds of work; and this is indispensable for soldiers in handling and using their fire-arms, during cold weather.

DIRECTIONS.—We present herewith (fig. 1) an engraving just **half the size** for an ordinary mitten. **Yarn.**—For Army Mittens, grey or blue mixed yarn, No. 20, or coarser, is recommended, though any color but white will do. They may be knitted or crotcheted. **Knitting Needles.** No. 15 are about the right size.—**Weight,** 3 ounces at least.—**Length,** 11 to 11½ inches.—**Width** over palm of hand 4½ to 4½ inches.—**Wrist,** or **Cuff.** Put 22 stitches on each needle, of No. 20 yarn, or more or less if the yarn be finer or coarser than No. 20. Rib 2 to 2½ inches for length of wrist or cuff.—**Thumb.** Begin the thumb at *A*, by making 2 stitches for seams, and widen 2 between seams, every four times round, until you have 20.—At *B*, drop 20 *thumb* stitches, and cast on 8 *new* stitches to increase width of hand.—**To Finish Thumb,** take up the 20 stitches dropped at *B*, and add 8 new stitches.—**Finger.** At *C*, drop 16 stitches for finger, and cast on 8 new stitches.—**To Finish Finger,** take up the 16 stitches dropped at C, and add 8 new stitches.—**To Finish Hand,** begin to narrow at D, but keep the width well up to the end.—The exact directions for finishing off the thumb, finger, and hand, we can not give. Our engraved pattern will be a sufficient guide, remembering that it is *just half of the average size.*

Any person desiring a pattern of full size can receive one free of charge by addressing John J. Hinchman & Co., at 26 Vesey-st., N. Y. City, to whom we are indebted for the directions.

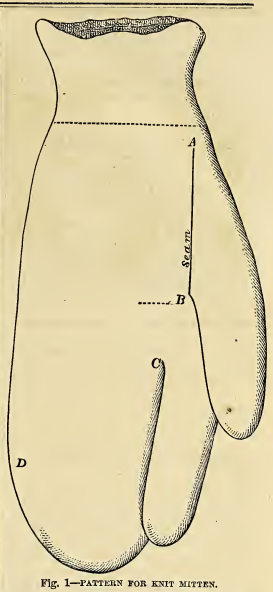

Fig. 1—PATTERN FOR KNIT MITTEN.

Cloth Mittens with one Finger.

These are very easily and cheaply made, and answer an excellent purpose. With a hand needle a woman can make up a dozen pairs or more in a day, and with the aid of a sewing machine the number may be more than quadrupled. The cost of making is so little that it pays to use up even old cloth—the skirts and back of a coat, the wider portions of pantaloons etc. We have from the Office of the Willcox & Gibbs' Sewing Machine Co., a full-size pattern, which we have *reduced exactly one-fourth.* Only two pieces of cloth are required, though the cloth, if too small, may be pieced out before cutting. Cut the larger piece like Fig. 2. When folded over from the dotted line, *a* matches *a*, and *f* upon *f* forms the cot for the forefinger.

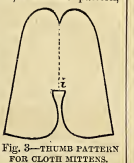

Fig. 3—THUMB PATTERN FOR CLOTH MITTENS.

The semicircular piece, *t*, is cut so far as marked, and then turned up against the inside of the thumb, giving a double thickness just where most used. Fig. 3, is a pattern for the thumb.

DIRECTIONS.—First sew the round piece (*t*) on to the outside of thumb (at *t*); then close up the thumb on the back, and fit it to its place (in *t*,) where it must be firmly stitched. Next close the side and finger by stitching around. The directions before us advise to leave the edges of cloth *outside* as they shield the sewing, while this secures a better fit. It will not look so neatly, though the appearance is not of much account. The folding is to be one way for the right-hand, and the other way for the left-hand mitten. A little practice with paper, and then with any cheap cloth, or common brown muslin, will enable any one to get a very neat pattern

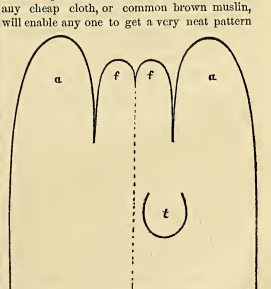

Fig. 2—PATTERN FOR CLOTH MITTEN.

in an hour or two. Half a million pairs would doubtless be welcomed by the soldiers who are handling cold weapons in this chilly weather. If our girls will get up plenty of these mittens for their fathers and brothers, so that they can have

a change every time their mittens get wet with snow and cold rains, they will confer a great favor. They may, if they please, stitch together as many kinds and colors of cloth in a pair of mittens, as there were in Joseph's coat. Willcox & Gibbs, N. Y. City, will supply full-size patterns free.

More About the Sock Pattern.

"Ready Knitter" writes, that the pattern and directions for knitting socks, given in the Dec. *Agriculturist*, are entirely orthodox, so far as they go, as was proved by several sets of nimble fingers she saw at work upon the socks after the appearance of the paper. They understood all the directions, and followed them until they got through with: "Knit as many times across as there are stitches on, then narrow five times." But what then? Surely, not bind it off; it would take a veteran square heel to fill out such a sock. "Ready Knitter" completes the directions thus: "For the heel, knit as many times across, as there are stitches on; narrow gradually, two stitches on every needle, (not the seam needle,) until the number is reduced one-half; then bind, and you will have a round, well-shaped heel."

For the American Agriculturist.

Washing Quilts and Comforters.

"Don't look at this quilt, I beg of you," said an invalid lady the other day, as my eyes involuntarily wandered over a once handsome patchwork quilt, spotted here and there in an unaccountable way. "You see," she continued, "it was nearly night before we wet it on the last washing day, and the girl rubbed some soap on the dirty spots, and put it in the suds, and then forgot it until morning."

Now, if there is anything needed to drive a woman crazy, it is to see a pretty quilt, that she has worked at for days and months, and prided herself on, spoiled in the wash.

Every good housekeeper has her bed clothes washed in the morning, so that they may have the benefit of the whole day to dry, and then there is no danger of their being forgotten over night. Handsome calico quilts are generally supposed to have deep red, green, or orange colors in them, that contrast so well with the white; if they lie wet over night, or are left out in frosty weather to dry, ten to one, they will never look well again; but if hurried through of a fine morning, and dried before night, they will look almost as fresh and new as they were when first made. A friend has a pretty quilt that was taken for a new one not long since, but she said: "The quilt is thirty-three years old, and was pieced by my mother before she was married; it has been washed a score of times, but I have never used it much because the hands that pieced it have long since rested from their labors."

And to young housekeepers let me say, always *try* your calico by thorough washing before putting it in a quilt, and, except for a comforter or common quilt, never use calico that will not stand boiling.

I believe in pretty quilts, and think they are an important feature in the beauty of the house, just as much as wall paper, painting, or pictures. For a spare bed-room, or "stranger's room," I remember a mother that always used a white Marseilles for the top quilt, and it was the most simple and elegant. In common bed-rooms, a calico quilt looks clean longer, is less expensive, and answers the purpose equally well.

And now a word as to comforters. I think they are the most expensive bedding people use, though they come the cheapest. What housekeeper does not look back this snowy day to her Fall washing of bed clothes, and think of the sigh of relief she heaved when through with it; and the *comforters*, she dreaded them more than all the quilts and blankets together. There are fine lamb's wool blankets in my house to-day that have been in wear half as long as I have myself; they have worn out several sets of comforters, and have been far more *comfortable* and certainly cheaper and cleaner. It is impossible for a woman to get a comforter right clean, except by ripping it out, washing the batting, and making it over; and this is one hard day's work for the best hired girl she ever had.

The fact is, we dread the washing of our comforters so much, that where we wash our blankets and quilts twice, we only wash the comforters once, though they need washing the most, from the fact that they hold, in their thick folds, more of the perspiration and impurities that escape from our bodies during sleep.

Carroll Co., Ill. MRS. M. J. STEPHENSON.

Double Glazing vs. Double Windows.

As usually constructed, double windows interfere with ventilation of living rooms, for seldom indeed is there other provision for a supply of fresh air. Now instead of using double sashes, if we simply put in double pieces of glass (one on the outside and one on the inside of the same sash) we may raise the sashes as usual. Two thicknesses of glass with the quarter inch space of air between them will keep out a great deal of cold and save fuel. At the same time the rooms will be likely to become warm while the air is still pure, and the result will be, that in order to cool them a sash will be lowered, and thus a supply of pure air maintained. When a single thickness of glass is all that defends us against the temperature of zero, which prevails without, the air of the room is so rapidly cooled that admission of fresh air is prevented by all possible means. The windows are "calked," the doors are "listed," and every thing made as close as possible. By having the windows double glazed, the obstruction of the view by the accumulation of frost is nearly if not entirely prevented.

A Cellar.

Whoever is at housekeeping, even in the most humble way, will appreciate a good cellar. There are multitudes, nominally keeping house, who really have nothing to do with housekeeping; these are they who build fine houses, and follow and set the fashions in such things. We need cellars to preserve things which must be kept at a uniform and rather low temperature, and which are benefited, or at least not injured, by moist air. The cellar should always be cool, moist, dry, rat-proof, well ventilated, and light or dark at pleasure. To secure these qualities it should be below the surface of the ground, with cemented walls and floor; if in wet ground, the water should be cut off by drains in the foundations, and the floor should have slope enough to carry off into side drains water spilt upon or used for washing it.

Cellars are often dry in Winter and moist in Summer, because, as the season changes, they are either warmer or cooler than the outer air, and so part with or attract moisture. On this account, ventilate cellars on moist, warm days in Winter. The introduction of hot-air furnaces into cellars to warm the rest of the house, has the effect direfully to warm and dry the cellars, and entirely ruin them for keeping vegetables, fruits, cider, etc.; and the modern fashion of basement rooms and cellar kitchens which is prevailing to some extent even for country houses, is equally ruinous. If a cellar kitchen is desirable, dig a cellar beneath it.

WHAT MAY BE KEPT IN A GOOD CELLAR.

1st. *Fruits*—particularly apples.

2nd. *Roots*—potatoes, turnips, carrots, parsneps, beets, salsafy, etc., the most sensitive of which, if packed in earth, will scarcely grow at all until near Spring, and will not shrivel a particle.

3d. *Growing Plants.*—Cabbages, cauliflowers, and broccoli, which will gradually head and come to perfection during the early part of Winter; celery, which grows and bleaches as it never does out of doors; endives, which, taken in and planted in beds, grow without care, beautifully blanched, and form a most delicious winter salad; and to these may be added leeks, chives, parsley, and many other plants.

4th. Cider, wines, bottled fruits, etc.

5th. Many tender plants, which will not bear our winters, as for instance, all tender roses, pelargoniums and geraniums, oleanders, lemon-scented verbenas, jessamines, *Daphne odorata*, etc. All these, and yet we have hardly begun to tell the uses of a cellar, never wet, never dry, never warm, never cold, never airy, never close, and dark or light at pleasure. We regard such a cellar as indispensable to economical housekeeping, but as a *luxury* is it not worth enjoying?

For the American Agriculturist.

Rat Proof and Water Tight Cellars.

In the foundation of the cellar wall, it is often and wisely recommended to lay a course of flat stones below the surface of the cellar floor, projecting four or five inches beyond the rest. If rats dig under the foundation from the outside, to come up on the inside, they will strike their noses against this projecting ledge, and supposing the whole floor to be made of quarry stones, they will back down and give up. This will answer in most cases; but to make sure work of it, and besides to get a dry and smooth cellar floor, it is advisable to cover the whole cellar bottom with water lime cement.

And this is the way to do it. If the house is already built, and the cellar is rather low between joints, it will be best to excavate and deepen the whole surface three or four inches. Having made a new smooth surface, sloping a little towards one corner, for the benefit of drainage, bring in a load or two of small cobble-stones, say of goose-egg size, and spread them evenly over the ground. Then put on a layer of coarse gravel and rake it down smooth, preserving, carefully, the slight descent to one corner, where there is to be kept an open outlet into the cellar drain.

Now prepare the cement, a little at a time, using the best of materials, and mixing two parts of hydraulic lime with three parts of clean sand. Spread it on about two inches thick, as soon as mixed, leaving the work finished smooth as you proceed. At the sides of the cellar, plaster up the walls eighteen inches from the floor. Make a shallow gutter in the cement all around next to the walls, to carry off any water that may chance to get on the floor. This gut-

ter is to terminate in the lowest corner of the cellar. At that point, a round hole (say two inches in diameter,) is to be made through the cement, and leading into the cellar drain. This hole is to be kept plugged tight (rat and mouse proof,) except when it may be needful to draw it for letting off surface water. Or better, it may be protected with a wire screen, or close iron grating to shut out the entrance of vermin.

In a month or six weeks, this plaster will be hard enough to bear walking upon; but at first, it is best to lay down a few boards. In two or three months the floor will be as hard as a rock. It can then be swept and scrubbed as often as one may desire. Rats and mice can not dig through it. Water from beneath will not penetrate it. It will be a daily and perpetual help to good housekeeping. X.

REMARKS.—(1) It strikes us that it is nonsensical to suppose rats will calculate the thickness of the wall, and give up in disappointment if it prove to be six inches wider at the bottom than above. (2) A smooth solid cement floor as recommended, is excellent every way, and contributes to neatness, purity of air, and the good keeping of vegetables. Wherever hydraulic lime is accessible, it is advisable to use it. The layer of cobble stones adds to the solidity and firmness of the bottom, but it adds to the expense also, and is not indispensable. We have seen many good cellar floors made by simply plastering with hydraulic cement directly upon the ground. (3) We have found by experience that a coat of cement, however good and thick upon the walls, will not keep water from breaking through, if the ground around be wet and springy. A drain outside the walls is the only help under such circumstances. The best protection against rats is to bed the bottom course of stone in cement, and have some of the cement below and behind the lowest tier of stones. A grouting or thin mixture of hydraulic lime, poured in among the loose earth behind the wall, will render it rat-proof.—ED.]

Moist air in Dwellings.

Who does not enjoy the summer-like air of a green-house, or well kept conservatory? It is so refreshing because it contains an abundant supply of moisture. We may secure an atmosphere very like this in our houses, if we will only make provision for free evaporation of water upon the stoves or in the hot-air furnaces by which they are warmed. Few people who keep water thus evaporating provide enough of it, and the result is, they do not realize any great benefit. In rooms, the air of which is properly moist, almost all common green-house plants will thrive, and we may have the fragrance of flowers in addition to the pleasant and healthful moisture.

Sea Weed Blankets for Dwellings.

M. E. Legou, in a recent report to the Paris Academy of Sciences, advocates the use of sea-weed between the thin outside walls of houses, for protection against sudden changes of temperature. This substance when not exposed to the light is unchangeable, does not ferment, will not readily take fire, and is entirely free from insects. Nothing is needed to prepare it, but a washing in fresh water to remove the salt, which would otherwise cause dampness. It has already been successfully applied between the tiles and ceiling of a railway station, in a portable house for camp use, and in the enclosures of temporary barracks. It is easily obtained along our whole coast, and may prove of important service in rendering the cheaper class of dwellings more comfortable.

Age of Meats.

We do not mean from the birth, but from the butcher. The Englishman would insist upon having his *beef* at least a week old, if the weather be not especially hot; his *mutton* not less than a month old; and other meats of such age as he has found them most savory to *his* taste. People of other nations think that meats require time—some more, others less—to come into their best condition for the table. In this country there is much more dread of *tainted* than of *tough* meats. While shunning Scilla, we have approached too near Charybdis. We often butcher in the evening and devour in the morning; and sometimes eat for breakfast that which was killed at sunrise. Except in case of necessity, this is not wise. Meats do not come into that condition in which they are most readily assimilated, and most nourishing, until some time after slaughtering—longer in cold than in warm weather, and longer with some kinds than with others, at the same season. Until then, they are tough, and although "there is no disputing of tastes," it must be admitted that they are, to a large majority of persons who have fairly made the comparison, less tasteful, if not absolutely unsavory.

For the American Agriculturist.

Rolled up Beef.

Cut pieces of beef, about as broad as a hand and ¾ inch thick, pound well, and add pepper and salt. Cut slices of bacon of the same size as the beef, roll the slices together, and tie them with a string. Boil with water enough to cover the meat; keep in a pot well closed. When the beef is tender, take it out, and also half the liquor; let the other half boil down, and then add the first half to it. Season with onions and salt to taste. Cut the strings off the beef and put on the table with the gravy. If to be used on the second day, boil it up again, cutting a pickle in the sauce, and it will be just as good. If to be kept for a time, put it in a dish and cover with fat. It will keep good for several weeks. MRS. NITZ.

Jefferson Co., Iowa.

How to Cook Eggs in the Shell.

A correspondent of the *Agriculturist* writes: "One way to cook eggs is to drop them into boiling water, and let them remain there three minutes—the water all the time boiling. This hardens the white next the shell to almost leathery toughness, while within it is still uncooked. Another and preferable mode is, to pour boiling water upon the eggs; let them stand in this 5 minutes; pour off this and add more boiling water and immediately bring them to the table *in the water*. Those taken out at once will be somewhat cooked through; and those left in five minutes will be "hard boiled," or nearly so, and thus the taste of every one may be suited and no toughness of the whites be observed."

PENNY WISE, POUND FOOLISH.—Undigested food in the stomach is sure to produce restless unrefreshing sleep, yet for the mere pleasure of tickling the palate for a few minutes longer while swallowing a little more food, how many suffer all night, and the next day also.

Cooking Indian Corn.

It may be well to state briefly here, what was more fully explained in last volume, viz.: that taking the average prices throughout the country, 40 cents worth of Indian corn meal, affords as much real, healthful *nourishment*, as $1 worth of wheat flour, or $1.00 worth of potatoes. Hence the importance of learning to use more corn for food in these times. In the November *Agriculturist* we gave thirty-three methods of using corn, or corn meal. An objection to many of the directions given, was that they called for considerable quantities of milk, or eggs, or both, and these are not always accessible or cheap. We hope our offered premiums will bring out something valuable on this subject. But this inside sheet must be sent to press before the exhibition opens, and our report, if published this month, must go in out of place on the outside sheet, which is sent to press ten days later. In the meantime, we desire to solicit further contributions of recipes or directions on this topic. Here are a few of those, gathered from our letter files.

Indian Loaves, *that will be good when four days old.* Sent to the *American Agriculturist* by Mrs. L. G. Smith of Essex Co., Vt. Take 2 quarts of Indian meal; 1 pint of sifted wheat bran; ½ ten-cupful of molasses; ½ teaspoonful each of salt and cooking soda or saleratus. Mix with sweet milk enough to make a batter as stiff as can be readily stirred with an iron spoon. Bake 6 hours.

Another Indian Loaf.—Contributed to the *Agriculturist* by Sarah Fuson of Fulton County, Ill. who has tested it satisfactorily for ten years past. Take 4 to 6 quarts of Indian meal and scald two thirds of it, stirring thoroughly with an iron spoon; cool with cold water until it will not cook the yeast, and add one pint good salt yeast. Stir in the remainder of the meal; put in a pan to rise, the same as light wheat bread, and afterwards bake well, and keep in a cool, dry place. Good when one to four days old.

Corn Meal Griddle Cakes.—J. S. Gerver, Williams Co., O., contributes the following to the *Agriculturist:* Take 3 cups of Corn meal, 1 cup of wheat flour; 1 cup of sour cream; 1 cup of sugar; 3 eggs; 1 teaspoonful of saleratus, and 1 teaspoonful of salt, with sweet milk enough to make a thin batter. Bake the same as Buckwheat cakes. It is good. [This must be very good when the eggs and cream are plentiful.—ED.]

Chicken Salad.

A friend who tried a chicken salad with us the other day, asked a minute description in the *Agriculturist* for the benefit of his better half and others. The recipe is a common one, for ought we know—perhaps it was used with special skill in the instance when our friend was so well pleased. Written minutely it reads thus: Mince finely the white parts of one chicken previously well boiled. Take blanched, crisp celery and chop very fine. With 1 measure of the minced chicken, mix 1½ measures of the chopped celery. Boil hard one large or two small eggs, roll the yolk fine, and mixing in a teaspoonful of mustard, and nearly as much salt, with ½ teacupful of vinegar, pour this over the chicken. Cut the boiled whites of the eggs in rings and lay on top, garnishing also with the smaller leaves of the celery.—Usually the celery is not chopped half fine enough.

Apple Pie without Apples.

One cup of water, one cup sugar, juice and peel of one lemon, 1½ or 2 Boston crackers broken into small pieces; bake with under and upper crust. The pieces of cracker look like apple when the pie is baked. The addition of a little stewed apple makes the deception complete—to eye and taste.

"IT SNOWS."
(Engraved for the American Agriculturist.)

The Editor with his Young Readers.

We wish "A HAPPY NEW YEAR" to you all, Young Friends. And we mean what we write. These words are often uttered flippantly, or for form sake; but just now we are both earnestly desiring the happiness of those who are to constitute the junior members of the great *Agriculturist Family* for 1863, and also seriously asking ourselves, what can we do to make our young friends really happy. We shall try to interest you somewhat, with short stories, anecdotes, puzzles, etc., which may be likened to the toys, nuts, candies, and sweetmeats, of an entertainment; but then the mind as well as the body needs some more substantial food—bread, meat, etc. An old and very true proverb is, that "All work and no play makes Jack a dull boy." Let us read it differently thus: All play and no work (or study) makes Jack a—*a what?* We will let you answer.

Start Right.

George, James, John.... Mary, Susan, Jane.... and all the rest! We suppose each one of you think now—as we often thought, when a boy—that you will do better in 1863 than you have done in any former year. That's right. We all ought to determine to improve more and more in every year that passes along. But mere wishing, and resolving, will never accomplish any good. Suppose James *wishes* to go a fishing, and having obtained permission from his parents, *resolves* to go early to-morrow morning. Does he rest satisfied with the wish and the resolution? No. He begins to think about the hooks, and lines, and poles, and bait. And he not only thinks and plans about them, but he goes to work at once in hunting them up and getting them ready. He lays specific plans, and begins to *do something*. In the morning he is up, and he *does something* at once; and he *keeps doing something* all day—walking, hunting a good place, or patiently holding the pole until his arms fairly ache, and at night he is rewarded with a heavy string of good fishes. What would you think of him if he sat still all the previous evening, and all the morning, and all the day, *thinking* how nice it would be to have a glorious nibble, and to haul out plenty of big fishes, and to bring home a string full? But how many boys and girls (and grown people too) sit and think over how nice it would be, to be kind hearted, obedient, amiable, lovable, to be able to curb an angry spirit, to avoid profane and unseemly words and thoughts, and to speak kindly to every one, even to the brutes; to do acts of kindness—in short, to have a good heart. Yet how often do they rest satisfied with the wish and the resolve, and even take credit to themselves for having these good wishes and resolutions, but *do* nothing. Now, young friends, when you think over some bad habit you wish to overcome, or some good habit you would wish to aquire, set right about the work of accomplishing the end. Lay your plans, just as James planned his arrangements for fishing. Begin now, and "hold on until the arm aches." Don't say, to morrow, or next week I shall begin, but begin *now*. Does that quick temper trouble you, set a watch over it now, and the very first time it begins to rise, remember your resolve, and check it at once. Keep repeating the same effort, every time there is occasion, and by and by you will master it. Hold the pole until your arm aches, and you will catch the desired fish. Firm resolutions, with well defined plans, and prompt action, will accomplish wonders. *Start right.* Begin *now*; keep at it through the year; and at its close, if you live till then, you will look back with pleasure upon the year 1863. Begin now, to day, this hour. *Start right*, and then hold on even "if the arm does ache."

An Adroit Thief.

A thief in England, who had been long watching an opportunity to steal from a certain house, one day saw both the owner and his wife go out, and immediately entered the premises to improve the opportunity. He proceeded up stairs and seized a feather bed, the most valuable article he could see, and commenced carrying it down stairs, walking *backward*. When about half way down, the owner entered the front door, and exclaimed, "Here you rascal, what are you doing?" "Taking this bed upstairs sir," was the reply. "Mr. Jones who says he is an old friend of yours, and is coming to spend a few weeks with you, sent me here to bring his bed." "Mr. Jones! I don't know Mr. Jones; what right has he to invite himself into my house? Clear out. "Very well, sir," replied the thief, coming down stairs with the bed, "but Mr. Jones will be powerful mad." And away he went with his load, leaving the family to discover their loss at bed time.

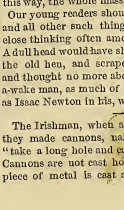
The Adopted Larks.

A gentleman in England relates that he found a nest full of young meadow larks, the mother bird having been killed by a stroke of the scythe while on her nest. It happened, that a robin had made her nest near his dwelling, and had just commenced sitting. He took the young larks, and watching his opportunity when the robin was away, removed the eggs, and putting the birds in their place, remained near to watch the result. The robin soon returned, and was just about to hop in, when she discovered the birds. She raised her wings, and stood as though greatly astonished. She looked at them first with one eye, then with the other, turning her head in a most comical manner. In a few moments she flew swiftly away, but almost immediately returned with the male robin, who manifested as much surprise as his mate had done. They chirped and chattered together at a great rate, earnestly discussing this unexpected state of affairs, and then suddenly darted away. The gentleman supposed they had decided to desert the little foundlings, but presently they both came back with food in their bills, and from that time reared them as tenderly as though they had been their own.

Whitening Sugar—A Curious Discovery.

The common sugar of our tables is made from the juice of sugar-cane, which grows only in very warm countries. This sugar cane resembles the stalks of our Indian corn, though its juice is much sweeter. In making sugar, the cane is cut into short pieces, and passed through a mill to press out the juice. This liquid runs off into a reservoir, from which it is dipped out into boilers, and boiled down. This process sends off the watery part of the sap in steam, leaving the sugar behind. When it is boiled down to syrup, this is put into large wooden trays called coolers. Here it becomes grain sugar.

But what a dark, dirty, brown mass it is! Can it be whitened? Yes, and here we will tell how man first learned to do it. A hen that had walked through a puddle of clay and water, went into a sugar-house, and walked over a pile of brown sugar. Some one noticed that wherever she stepped, the sugar was whitened. This man opened his eyes wide, and by several experiments soon discovered the fact that moist clay would whiten sugar!—And that man's discovery led on to a systematic use of earthen jars, shaped like the annexed cut, and hence came the old-fashioned "loaf-sugar." The raw sugar is put into one of these long jars, with the widest end upward. When the jar is nearly full of sugar, clay is put on the top and kept constantly wet. The water runs through the clay and sugar, and finds its way out through a small hole at the bottom of the jar. In this way, the whole mass of sugar becomes white.



Our young readers should watch even hen-tracks, and all other such things, for sharp looking and close thinking often amount to something useful. A dull head would have shouted "Shoo!" shoo!" to the old hen, and scraped off her muddy tracks, and thought no more about it. Not so this wide-a-wake man, as much of a philosopher in his way, as Isaac Newton in his, when he saw the apple fall.

*

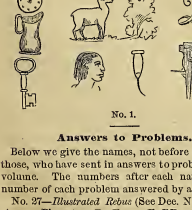
The Irishman, when asked by some jokers how they made cannons, naively answered that they "take a long hole and cast some iron around it." Cannons are not cast hollow at all, but one solid piece of metal is cast and afterward bored out.

A Boy Regiment—Good.

We have just heard that in a certain County (name and location not given,) there were a large number of patriotic boys, very desirous of doing something for their country in these times; but their ages, (13 to 16,) prevented their being received as volunteers in the army. But they did the next best thing. A regular regiment was formed, with Colonel, Major, captains, lieutenants, corporals, etc., and all were fully armed, not with guns and swords, but with good buck-saws and axes,—a few of them as "engineers" and "sappers and miners," carried beetles and wedges. They organized under the name of "The Wood Cutters' Regiment." Thus organized, they sent out all through the county, "scouts," who hunted up every family from which an adult had gone forth to the war. The volunteers then separated into "divisions," "companies," and "battalions," and commenced a vigorous assault upon the wood-piles of all these families, and made short work of cutting up a good winter's supply of fuel. "Foraging parties," with teams, procured and hauled wood, where a supply was not on hand. The regiment will not disband before Spring, but keep up the battle until the enemy, under Gen. Frost, is compelled to retire to the northern borders of Queen Victoria's American Possessions. Good for these young soldiers, we say. Here is an example worthy of universal imitation. Let us have such a regiment in every county in the country. Send us the names of the regiments, and the officers, and we shall gladly publish them in our roll of honor. Every private in such a regiment will be a "high private."—One hint more. While about it, don't stop with the families of soldiers. Let the scouting parties enrol the name of every poor widow to be found, and let them be defended against any possible disturbance from Gen. Frost. We recall, with pleasure, the fact that in more peaceful times we once held a captain's commission, in a company organized to supply and cut wood for each family in the neighborhood whose natural provider was dead, or disabled by sickness. Never shall we forget the pleasure experienced by every member under our "command" when we deposited ten loads of wood at a door where the man of the house was sick, and the family were in bed at mid-day, *to keep warm*—their last stick having been burned up the day before. If boys ever chopped wood with a will, it was on the afternoon of that day. If ever boys went to bed feeling joyful, it was our company on the night of that day.—When, and where shall we hear from the second wood-sawers' regiment for this Winter?

Problems, Puzzles, etc.

Under this head we shall try to furnish some amusement, combined with instruction, for our young readers. Unfortunately we have only room in this paper for the Illustrated Rebus below, which conveys a good sentiment. It is so easy, that the very little folks can probably read it, we think.



No. 1.

Answers to Problems.

Below we give the names, not before reported, of those, who have sent in answers to problems in last volume. The numbers after each name tell the number of each problem answered by any one.

A Royal Barber.

Joseph II, emperor of Austria, was fond of traveling incognito, or in citizen's dress. One day he reached a little inn on his route, before the rest of his company came up, and entering into a retiring room, he commenced shaving himself. The inquisitive landlord was anxious to know what post his guest held in the emperor's retinue, and inquired. "I am his *barber*," was his majesty's reply.

Only a Sample.

The comic Burton, while sailing up the Hudson River, took his seat at the dinner table, and called for a beefsteak. The waiter brought him a very small piece, only enough for a taste. Mr. B. took it upon his fork, turned it over, examined it particularly, and with a comical look exclaimed: "Yes, that's it, bring me some."

"Fred," said a little four-year old, "give me sixpence to buy a monkey." "We've got one monkey in the house now," replied the elder brother. "Who is it, Fred?" asked the little fellow. "*You*," was the reply. "Then give me sixpence to buy the monkey some nuts." His brother "shelled out."

EXTRAORDINARY EXHIBITION.

"KING CORN" in Royal Array—Immense display of CORN BREAD, CORN CAKES, etc. Over 200 Specimens from all parts of the Country, with Specifications for Making each—Interesting and Valuable Information.

In November last we stated that, taking into account the current prices of Corn, Wheat, and Potatoes, in different parts of the country, West as well as East, and estimating the relative proportion of healthful nutriment furnished by a bushel of each, it seemed evident that

A similar amount of nourishment would be obtained from:

40 Cents expended in purchasing CORN.
100 Cents expended in purchasing WHEAT.
160 Cents expended in purchasing POTATOES,

and that with the present large crop of Indian Corn, and the great foreign demand for Wheat, it was especially important to use more corn for food, and save our Wheat to sell.—In order to call out information upon the best methods of *cooking* Indian corn meal, we proposed, in the *December Agriculturist*, to have an exhibition of Corn Bread, and Corn Cake at our office on December 14th.—Premiums of $10, $5, and $2, were offered for the best, second best, and third best loaves of Bread, consisting mainly of Corn meal; also an extra premium of $1 for the best loaf of Cake of any kind in which corn meal should be the chief ingredient. *A Special Cake Premium*.—As the extra premium of $4 for Corn Cake was limited somewhat by the *cost*, we afterward decided to add to our published premiums a special premium of $2 to be awarded to the *Best Corn Cake of any kind, without regard to cost*. The main requisites for the BREAD were to be: *cheapness*, fair quality, and adaptability to *general family use*, eaten cold, as well as hot, and when from one to three days old. Full directions for making were to accompany each loaf.

Not having advertised the exhibition, beyond the single announcement in this journal, and not receiving many responses in advance, we began to fear the war would divert attention from what appeared to us to be an important enterprise for the public. But Thursday morning (Dec. 12th,) specimens began to arrive; Friday morning the Express Companies, and others, called freq ently, with from one to a dozen loaves; Saturday morning the inflowing current grew stronger and larger, until finally the entries reached over *two hundred* (**219**). Several entries being for duplicated loaves, the entire number of specimens reached some **250**! As will be seen below, these came from the distant West, from the Middle States as far South as Maryland, and from the North and East. A space of *seventy four feet* of wide table room was closely filled with a most imposing display of loaves of all sizes, from nearly half a bushel down to patty-pan corn meal biscuits, and small corn meal crackers—and not bad crackers either. There were pure corn meal loaves, and loaves of "Rye and Indian;" loaves one part wheat or rye flour with three parts corn meal, and loaves apparently half meal and half flour, with loaves of every intermediate combination. There were pumpkin loaves, corn meal dodgers, corn meal pound cake, corn meal pone, corn meal crullers, corn meal "nut-cakes," corn meal baked puddings, and corn meal what-nots. There were round loaves, square loaves, high loaves, and flat loaves—in short, loaves of every conceivable form and shape, for of the two hundred and fifty-odd specimens, scarcely two were alike in form and mode of making. The sight was one to gladden not only the hungry, but to cheer the heart of every patriot when he remembers that corn is our native cereal, that it grows every where and in abundance, that it is at yet untouched by any disease, that it is healthful and nourishing, and that to-day one, with cash, can buy from ready sellers at the West, more bushels of corn at 15 cts. a bushel than there are bushels of wheat now on the Continent. The exhibition showed at a glance the great variety of palatable forms in which corn meal can be worked up.—Under or by the side of each specimen were placed the directions for making it. The large concourse of visitors, numbering by thousands, were both surprised and gratified, and many went away resolved to henceforth largely increase their family purchases and use of corn meal. The general feeling seemed to be that of a good farmer housewife from Central New-Jersey, who brought in a noble loaf, expecting to get the first prize among a few competitors. She exclaimed "Wall, wall, this beats all. Why I'd hold a thought it? I always stood up for using corn, but I never did think so *many* things could be made of it. Corn IS King." *We* certainly felt much as she did.

At the urgent request of many gentlemen who wished to bring in their wives and daughters, we concluded to continue the exhibition over until Thursday, and on the evening of that day handed over to the Ladies' Five Points Mission enough to feed many hundreds of poverty stricken ones under their care or over-sight—a source of satisfaction certainly to the many whose fair hands had mixed and fashioned these loaves. The good keeping quality of most of the specimens was well tested by this delay.

The general results of the exhibition can but be widely useful, not only to the visitors, and to our own readers who will, in future numbers of the *Agriculturist*, find a hundred or more of the best recipes, but the Editors of other journals were present and made notes, and will send abroad the hints and suggestions they here derived. The public notice thus drawn to the subject will awaken far more general attention to the value of Indian Corn. We regret that our January number is so nearly closed up that we can only give this month,

A CONDENSED GENERAL REPORT.

The specimens, as they came in, were entered in a book, numbered from **1**, upward, the name and location of the exhibitor removed, and the directions placed upon the table with the loaves. In this way the Committee of Judges had before them the directions for each specimen, while they had not the slightest clue to the name or location of any exhibitor. They made their notes and decisions by the entry *numbers* alone.

The exhibitors, at least, will be interested to see how that the committee of judges were carefully selected. The first named is a practical baker of Flushing, N. Y., of experience and good judgment; the second for a long time a baker of this City, was named to us by others in the same business, as one who would exercise sound discretion and good taste; the third, a well known farmer of Westchester County, whose large experience as an exhibitor, manager, and judge, at various agricultural fairs was useful as the overseer. The three ladies we know to be good housekeepers. The first-named resided long in the South, where they pride themselves on good "corn

ocan"; and the same may be said of the second, substituting West for South. Prof. J. A. Nash, formerly Agricultural Professor in Amherst College, acted both as judge and secretary to the committee, making careful notes of all the examinations. The Committee commenced their labors early on Saturday morning—cutting and tasting each specimen, and examining the specifications. They continued until a late hour, and on Monday morning they met and spent most of the day in going over the whole ground, to revise the notes of the previous day. So much for the general arrangements. We have this month only space remaining for the Committee's report, and list of exhibitors. To those who took the time and trouble, and incurred the expense of sending their contributions to this Exhibition, we desire to return hearty thanks, both for ourselves, and in behalf of the public, for we are assured that great public good will yet come of the interest awakened by the exhibition.

Judges' Report.

The undersigned, requested to act as a Committee of Examination and Award at the exhibition of Corn Meal Bread, Cake, etc., held at the office of the *American Agriculturist*, Dec. 14th to 18th, 1861, have discharged their duty to the best of their ability, and respectfully report: We found the number of entries 219, while the duplicate specimens included in the same entries raised the total number of specimens to about 250. We confess to a feeling of no little surprise and gratification at the large and interesting variety contributed. The long, closely packed tables presented a sight of unusual magnitude that we had ever before seen, or conceived. It has been truly gratifying, to us at least, to find how great the variety of uses that can be made of our great national cereal crop, and we are fully convinced that few persons can be aware how well adapted this material is to supply not only a cheap, wholesome diet, but also for making, with suitable additions, a great variety of most palatable cakes, etc. We found excellent corn meal pound cake, fruit cake, crullers, biscuit, breakfast cake, etc., in addition to numerous loaves of first rate bread made with various proportions of wheat or rye flour, eggs, sugar, molasses, pumpkins, etc. Of all the specimens exhibited, a large proportion were "fit food to set before a king," and there was not one that would afford any reasonable grounds of complaint to the most unreconciled to unsatisfactory "eat this or starve." Of the whole number, we scarcely found two exactly alike, either in form or specifications for making. The sweetness, lightness and good quality of several loaves three to five days old, consisting of one part of corn meal to from two to four parts of wheat flour, shows that this proportion may well be adopted not only in families, but in the food for soldiers; and we would respectfully suggest to those in charge of this department of the Government to look into the subject. The comparative economy in the use of which would soon save a hundred thousand dollars, in feeding our vast armies, while the small admixture of one-fourth to one-third of corn meal makes a much less tenacious, and therefore more healthful bread, than one composed entirely of fine flour.

CORN MEAL BREAD.

As the conditions of the premiums required *cheapness* as well as *fair quality*, we could not take into account a large number of excellent loaves of "Rye and Indian," wheat flour with meal, loaves containing eggs, etc. After selecting fifty of the best, and re-selecting again and again, we finally decided that Nos. 84, 21, and 198, came nearest to the requirements of the offered premiums. The specifications furnished were as follows:

No. 34.—"Take 3 quarts of corn meal, with about a pint of (thin) bread "sponge," and water enough to wet it. Mix in ½ pint of wheat flour and a tablespoonful of salt. Let it rise, and then knead well the second time. Bake 1½ hours."

This loaf was of beautiful form, cut light, and was of fair quality when three or four days old. Except in color and difference in taste, it resembled a wheat flour loaf.

No. 21.—"Mix 2 quarts of new corn meal with 3 pints of warm water. Add 1 tablespoonful of salt, 2 tablespoonfuls of sugar, and one large tablespoonful of hop yeast. Let it stand in a warm place 5 hours, to rise. Then add ¾ pint (or 1¾ teacupfuls) of wheat flour and ¾ pint of warm water. Let it rise again 1½ hours; then pour it into a pan well greased with sweet lard, and let it rise a few minutes. Then bake in a moderately hot oven, 1½ hours. It is *best* when hot."

This was a beautiful, almost crustless loaf, of a pleasant sweetish taste, and good quality. The bottom part was a little heavy, as if not baked quite enough, or not raised sufficiently, but a commendable bread, and rather more palatable than No. 34.

No. 198.—"Take 2 quarts of white corn meal, 1 tablespoonful of lard, 1 pint of hot water. Mix the lard in water; stir it well, that it may get heated thoroughly, and add ½ pint of cold water. When the mixture is cool enough, add 2 well-beaten eggs, and 2 tablespoonfuls of home-made yeast. Bake 1 hour, in a moderately heated oven. If for breakfast, make over night."

This, owing to the whiteness of the meal, and the lightness of the texture, as well as the general appearance of the loaf, greatly resembled the ordinary loaf of wheaten bread on our tables, and is worthy of general adoption where eggs are sufficiently plentiful.

For *taste and quality* the above three would stand in order of merit, 198, 21, 34. But taking into account not only taste and quality, but *cheapness* and *little trouble in making*, or "adaptation to general every day family use," we unanimously award as follows:

First Premium of $10 to Number 34.*
Second Premium of $5 to Number 21.
Third Premium of $2 to Number 198.

CORN MEAL CAKE.

In this class there were a great variety of specimens. Many of them were very good, and several must be *first-rate* when eaten hot or warm. As cheapness as well as quality were to be taken into account, we finally decided to award the

Corn Meal Cake Premium of $4 to Number 166, made as follows: "Take 3 teacupfuls of corn meal, one teacupful of wheat flour, 2 tablespoonfuls of brown sugar, 2 teaspoonfuls of cream of tartar, and 1 teaspoonful of salt. Mix well together *while dry*. Add 1 teaspoonful of soda (or saleratus) dissolved in warm water. Add the whole to a thin batter, and bake in a quick oven, ¾ hour. The same batter will bake quicker in patty pans, or on a griddle, like buckwheat cakes."

A Special Premium was placed at our disposal to be awarded to the best Corn Meal Cake of any kind, without regard to cost. This was a difficult task, as there were many specimens all worthy to be called "best;" but after extended examination and consultation, we unanimously agreed to award

Premium of $2 for best Cake of *any kind* to No. 125, Made as follows:

Take eight eggs, and their weight in powdered sugar; the weight of six eggs Indian meal; ½ lb. butter, and one nutmeg. Beat the whites and the yolks of the eggs separately; adding the whites last; bake one hour.

The Committee would gladly mention many other excellent specimens both of Bread and Cake, but we learn that it would render the report too long for immediate and general publication. We will, however, append to this report, memoranda made during the examination, which can be published hereafter, as we understand it to be the design to print in the *Agriculturist* a more full account of the different specimens. We must, however, call attention to No. 140, a most excellent cake or pudding suitable for breakfast, or for any other meal, as we found it delicious when eaten cold, and five days old. The directions are as follows:

No. 140.—"Take 2 cups corn meal, 1 cup wheat flour, 1 teaspoonful salt, 2 teaspoonfuls cream of tartar, 1 teaspoonful of soda, 3 eggs, 3 tablespoonfuls sugar, 1½ pints milk, and 1 tablespoonful butter. Rub meal, flour, salt, soda and cream tartar through a sieve, which will mix them thoroughly. Then beat the eggs and sugar together, adding to them the butter melted. Next add the milk, and last of all stir in the previously mixed meal, flour, salt, soda and cream tartar. Bake immediately and rapidly, to secure the escaping gas.) Twenty minutes will finish it in a brisk oven."

In conclusion the Committee desire to return their thanks in behalf of themselves and the public, to the proprietor of the *American Agriculturist* for originating and carrying out this most interesting and useful exhibition, and they award to him a special Honorary Diploma. Our own task has been a laborious and difficult one, but it has been cheerfully performed, and we have found ourselves intensely interested and gratified, and the knowledge we have ourselves acquired has rewarded our labors a hundred-fold. (Signed)

John S. Pittman, Mrs. Wm. T. Hemmenway, Alexander Lang, Miss Sarah C. Stewart. W. S. Carpenter, Mrs. } Committee.

New-York, Dec. 18th, 1861.

SUCCESSFUL COMPETITORS.

*The names of the successful competitors, which were wholly unknown to the Judges, are as follows:

No. 34.—Mrs. Jane O'Brien, Carrick, Allegany Co., Pennsylvania.

No. 21.—Mrs. Lott Cornelius, Locust Valley, Queens Co., Long Island, N. Y.

No. 198.—Mrs. R. Flanklin, Annapolis, Maryland.

No. 166.—Mrs. W. A. Jenkins, Bedford Avenue, Williamsburgh, N. Y.

No. 125.—Mrs. H. A Judd, Rome, Oneida Co., N. Y.

(We are glad to find a "nameless" successful in exhibiting the merits of "King Corn." Though wholly a stranger to us until after receiving the Judges' Report and referring to the clerk's entry book to find who sent in No. 125, we are inclined to think there must be some relationship, even though distant.—Ed.)

No. 140.—Miss C. A. Belknap, Kent-av., Brooklyn, N.Y.

As previously hinted, we shall hereafter publish many of the best recipes or directions in our regular Household Department. Owing to the late date, we can only find room now for the few recipes given in the Judges' Report.

LIST OF ENTRIES.

REMARKS.—The specimens were numbered as below, in the order received. In many cases the same contributor sent duplicate specimens of bread, cake, etc., so that the actual number of loaves considerably exceeded the numbered entries.—Through the fault of the express carriers, or otherwise, the specimens numbering above 207 did not arrive until Tuesday morning, Dec. 17, after the Judges had made their award. We suppose nearly all the contributions came from Ladies, but where only the initials were given, we are in doubt whether to write *Mr.* or *Miss*, and accordingly omit the prefix.

Market Review, Weather Notes, etc.

American Agriculturist Office.
New-York, Friday Morning, Dec. 20, 1861.

*** The materials for this review are furnished specially for the *Agriculturist* by a reliable man of long experience, who, throughout the year, spends the whole of each day in the markets, watching the transactions and collecting information, and we flatter ourselves that this report is one of the most correct anywhere published.

It will be seen by our condensed tables below, that the transactions in Breadstuffs in this market have fallen off, as compared with the previous month. This was, of course, to be expected, as the canals have been closed about half of the month previous to this date, and the receipts have necessarily been restricted. But in the second table we introduce a comparison which shows that business has been much larger in volume, than during a corresponding period last year. The increase is quite marked in the receipts of flour, corn, rye, and oats, and in the sales of flour, wheat, corn and rye. Of Barley the receipts have been heavier, but the sales much less. The sales of breadstuffs have been restricted, not only by a want of supplies, but especially by the high rates of freights to foreign countries on account of the risk of American vessels, by the difficulty at one time of selling bills of exchange, and recently by the news of excitement in England. It has been a matter of surprise even, that the prices are not more depressed in the present excitement. The table of prices below shows that flour averages scarcely 15 cents per barrel below the rates one month ago, while wheat, corn, and corn meal, are fully as high to day, as at the same date last month. But for the present unlooked for political disturbance abroad, prices would undoubtedly rule much higher, and should the present excitement blow over, without serious results, we shall look for a sharp upward turn of the market, owing to a positive and certain large demand, which can not be met with adequate supplies until spring navigation opens. So entirely convinced are the leading dealers in breadstuffs that we shall have only a diplomatic contest with England, that they hold stocks firmly .... There are few changes in the prices of the various articles of Trade. Cotton has advanced rapidly, owing to the very limited supply, and an active speculative demand....Wool has advanced 2 to 3 cents per lb. on some grades, with a good demand still prevailing....Pork has declined under the influence of the large receipts of live hogs at the market as noted below....There has been a fair demand and steady businesss in provisions, tobacco, hay, hops, naval stores, etc. The table below shows what changes have occurred in prices.

CURRENT WHOLESALE PRICES.

	Nov. 19.	Dec. 20.
Flour—Super to Extra State	$5 50 @ 6 00	$5 40 @ 5 85
Superfine Western	5 50 @ 5 65	5 35 @ 5 50

N. Y. Live Stock Markets.—The Cattle Markets have not been so over crowded with animals of late as previously. The receipts for the past 5 weeks have averaged 4,217 per week, or near 1,000 less than last month. Prices have gradually advanced nearly 1c. per lb. above last month's quotations. At the market of Dec. 18 there were many extra fat, or premium bullocks offered for "Christmas beef" which sold at 9c.@10c. per lb., estimated dressed weight. Good beeves, 8c.@9c.; ordinary 7c.@7½c.; and poor 5c.@7c. Average of all sales 8c. and everything sold off clean.

Veal Calves.—Receipts for the past 5 weeks number 2,809, or 562 per week, varying but little in supply or prices from the previous month. Good veals are worth 5c.@5½c. per lb. live weight. A mammoth calf, 8 months old, weighing 810 lbs. sold for $40, last Tuesday.

Sheep and Lambs—Receipts have fallen off largely, the average for the past five weeks being 11,143 per week. They have advanced materially in price, good fat sheep selling at 4c.@4½c. per lb. live weight—a few "Christmas Sheep," of over 200 lbs. live weight, sold at $15 to $20 each. Stock is scarce just now.

Live Hogs—Immense Receipts.—The receipts have been enormous—far exceeding anything before known in this market. The total receipts for 5 weeks have been **170,614**, or 34,123 per week, while the receipts for all of last year were only 319,620, or an average of 6,147 per week. The greatest receipts for any one week in 1860 were 15,180; the receipts for *this* week were 38,200. This influx to the market, is due to the embargo of the Mississippi, a usual outlet to Western pork, and to the disturbed condition of the slaughtering towns along the Ohio and upper Mississippi.—The slaughter houses of this City were, for a time, unprepared for receiving so many, but they are now able to dispose of all that come. Prices have continued to rule low, but are improving a little now. The selling rates this week are for corn-fed hogs 3½c.@3¾c. per lb. live weight. Still-fed 3c.

The Weather, has continued remarkably mild for a Winter month, with very little rain and only two light snows which disappeared with a few hours of sunshine ——Our Daily Notes, condensed, read: *November* 19 to 22, clear and warm—23, rainy day—24, clear and cool, 1 inch snow fell at night, but soon melted—25 to 28 clear, cool—29, rainy day—30, rain A. M., clear P. M.—*December* 1, clear A. M., cloudy P. M.—2, cloudy—3, clear cool—4, coldest day of season mercury 18°, first hard freezing—5, clear, fine—6, cloudy—7 to 10, foggy mornings, clear and warm, Indian Summer days—11, rain A. M., clear, cool P. M.—12, 13, cool—14 to 17, clear and warm—18, cloudy, mild—19, 20, clear, fine.

PREMIUM LIST,

For 1862---Vol. XXI.

Or Pay to Voluntary Agents who will attend to collecting names of new and old subscribers to the Agriculturist, and forwarding them to the Office.

(See List on next page.)

Experience has proved that it is a benefit to the subscribers themselves, as well as to the Publisher, to have an *Agent* at every Post Office, to attend to collecting the names and subscriptions of old subscribers, and to present the advantages of the paper to those not yet acquainted with it. But to employ and commission a Special Agent in every neighborhood throughout the country, is out of the question. We therefore offer certain good articles, the value proportioned to the number of names sent in, and leave them open to every person disposed to attend to the business, in the locality where he or she may be known to be reliable. By giving the articles offered we can make the pay *much larger* than if in money, because we have facilities for getting these articles at a low rate. Besides, the advertising thus given to the manufacturers, induces them to bear a considerable portion of the expense on the articles we need for premiums.

☞In selecting articles for premiums, we have aimed to get such as are *useful*, and as have been most frequently called for by our readers. ☞We wish it distinctly understood *that these premiums are offered in good faith—no cheap, trashy, imperfect, poorly made, or second-hand thing, will be sent out, but each article offered, is the best of its kind, and every one will be selected by the publisher from the very best manufactured. They will be the best sold in the market at the prices named.*

☞ We offer nothing *for competition.* Each premium is for a specified number of subscribers, and no one's remuneration will depend upon what other unknown persons are doing. Every one aiming for a premium, knows just what he or she is working for; and also that if a higher premium is not secured, a lower one can be taken.

☞Only one premium can be paid on the same subscriber

☞ *We make no distinction between new and old subscribers,* but it is expected that every canvasser will not only gather up the names of old subscribers, but also secure a large number of new names.

☞ Every person collecting names for premiums, should send the names with the money as fast as obtained, so that the subscribers may begin to receive their papers; but if designed for premiums, two copies of each list of names should be sent—one of them marked at the top "For Premiums," and also with the name of the sender.

☞ The premiums are offered for subscribers for Volume XXI (1862), *whenever received.* Canvassers will have time

for completing their lists, but the premium will be paid as soon as any club is made up—if duplicate lists are sent.

☞ Any person who has commenced sending in names at 80c. and finally fails to get the higher number of names, can fall back upon the smaller number, by remitting the 20 cents extra on each of the smaller number of names required.

☞ Clubs need not be all confined to one Post Office.

☞ No premium is sent till *specifically asked for*, as we have many friends who send in large lists but who will take no premium, and we are not certain that premiums are desired, unless the fact be mentioned particularly.

Table of Premiums for 1864.

Names of Premium Articles.	Premium. Price of each.	Names at 80 cts. each.	Names at 85 cts. each.
2—Clothes Wringer, No. 2	$7 50	18	37

25—Youth's Chest of Tools	$13 00	38	60
26—Gentleman's Chest of Tools	$20 00	60	80

DESCRIPTION OF THE PREMIUMS,—SEE REMARKS ABOVE.

Premiums. 2, 3.—Wringing Machine.

We place this first, for it is nearly new, and one of the most useful articles for every family. We had one of the first made, and have used it over a year with the highest satisfaction. It completely does away with the hard straining work required to wring out garments by hand. It does not twist and break the fibers of the clothes, but simply presses them between two elastic India rubber rollers, which are moved by a crank, and whether large or small pieces, they come out dryer than when wrung by hand The saving to garments would soon pay the cost of the implement, to say nothing of the saving of WOMAN'S labor. The machine is set upon the side of any tub; the garments drop out into a basket. A child can quickly wring out a tub full of clothes—No. 2, costing $7.50, is just the thing for common family use. This we present to any one sending us **18** subscribers for the *Agriculturist*, at $1 each, (or **37** at the lowest club price of 80 cents each).—No. 3, costing $10, is suited to larger families and Hotels. We will present it for **23** subscribers at $1 each, (or **48** at 80 cts. each.)

Premium No. 4—Sewing Machine.

90 Subscribers at $1 each, (or **130** at 80 cents each,) will entitle the person sending them to *Wheeler & Wilson's* best **$45 Sewing Machine**, (including **Hemmer**), new from the factory, and of the very best make. There is no better family machine than this made, as we have proved by nearly *four years'* use in our own family, in connection with other machines. We want no better.—The prolongation of life, the saving of health and strength to our females, and the better physical vigor thus secured to the next generation, render the Sewing Machine one of the most desirable additions to the household.—Premiums 4 and 5 will be selected new at the manufactories, be well tested, and forwarded without expense to the recipient, except for freight charges after leaving the city. Full instructions for setting up and using go with each machine.

Premium No. 5—Sewing Machine.

69 Subscribers at $1 each, (or **98** at 80 cents each,) will entitle the person procuring them to *Wilcox & Gibbs'* **$55 Sewing Machine,** including a set of **Hemmers.** This is the best machine of its kind, (sewing with one thread,) and has several points superior to other machines. It is neat, well made, simple in its operation; and having tested one in our own family for more than a year, we think highly of it, and can recommend it to those who can not afford to buy the higher priced double-thread machines. (The regular price of this machine is $70, but we have included in our offer $5 extra for the set of *Hemmers*, because those used with this machine are very simple and effective, and should go with every machine sent out.)

Premium No. 6—Barometer.

19 Subscribers at $1 each, (or **24** at 80 cents each,) will entitle the person getting up the club to one of *Kendall's* **Aneroid Barometers,** (Price $7.50.) This is a good, portable instrument, and valuable to every person as a weather guide, as well as for scientific purposes. We have had one in use for nearly two years, and find it very accurate, but an admirable weather prophet. Scarcely a rain storm or gale of wind has occurred, that has not been heralded by the barometer. Each instrument is packed in a neat leather case, 6 inches square, and 4 inches deep.

Premium No. 7—Hydropult.

30 Subscribers at $1 each, (or **44** at 80 cts. each,) will entitle the person making up the club to the **Hydropult,** (Price $12,) a very useful hand implement for carrying instantly to any desired point, to throw water from a pail, tub, cistern, or other receptacle, for extinguishing fires, watering plants, washing carriages, etc., etc. A stream can be thrown up to the third story windows. It is has jet pipes, and sprinkler; is made of brass, and is durable. It weighs 8 lbs., and can be packed in small compass to go by express or otherwise.

New-Orleans and Vicinity---Ship Island.

Premium No. 8—Melodeon.

125 Subscribers at $1 each, (or **237** at 80 cents each,) will entitle the person getting up the club to one of *Geo. A. Prince & Co.'s* **$75 Melodeons** (3 octaves). These Melodeons are of very superior tone and finish. We have ourselves used one for two years past, and it has given the highest satisfaction, and is pronounced by all who have heard it, as one of the very best. The different priced instruments are of equally good tone—the price varying with the size and style of finish. The size, prices, etc., of these instruments can be learned particularly, by sending a stamp to Geo. A. Prince & Co., Buffalo, N. Y., for an illustrated descriptive catalogue. The instruments given as Premiums, will be sent new directly from the factory at Buffalo, ready boxed, and without expense to the recipient, except for freight.

Premium No. 9—Melodeon.

104 Subscribers at $1 each, (or **183** at 80 cents each) will entitle the person getting up the club to one of *Geo. A. Prince & Co.'s* **$60 Melodeons** (4½ octaves.) See No. 8.

Premium No. 10—Melodeon.

90 Subscribers at $1 each, (or **130** at 80 cents each,) will entitle the person getting up the club to one of *Geo. A. Prince & Co.'s* **$45 Melodeons** (4 octaves.) See remarks above. **N. B.**—Higher priced Melodeons will be given for larger lists, in the same proportion.

Premium No. 11—New Cyclopedia.

96 Subscribers at $1 each, (or **140** at 80 cents each,) will entitle the person getting up the club to a set of *Appleton's* **New American Cyclopedia**, now in course of publication, consisting of *sixteen large volumes* of 770 pages each. This is a magnificent work, forming a whole library embracing every topic of human knowledge. Twelve volumes are now ready, and the remaining four will be furnished as fast as issued. The original design of this work was 15 volumes, but it is found that the immense mass of matter will require 16 large volumes. The work is sold at 83 per volume, or $48 for the set. To no better purpose could any one devote the Winter evenings than in raising a club of subscribers to secure this for himself and family.

Premium No. 12—Best Dictionary.

18 Subscribers at $1 each, (or **40** at 80 cts. each,) will entitle the person getting up the club to a copy of the *large Pictorial Unabridged Edition of* **Worcester's Dictionary.** (Price $7 50.) This now stands confessedly the most valuable Standard Dictionary published. It weighs nearly **10** lbs., is **13** inches long, **10** inches wide, nearly **4** inches thick, and contains **1854 pages** of 3 columns each, giving the spelling and pronunciation, with full explanations, of every word in the English Language, and as a source of general information on all subjects, stands next to the Cyclopedia. The Dictionary can be called for at our Office, or be sent by Express or otherwise, to any part of the country.

Premiums Nos. 13 to 17—Back Volumes.

These premiums (13 to 17,) will enable any one to secure the previous excellent volumes of the *American Agriculturist*, as far back as Volume XVI. We have stereotype plates and can print any number desired of the English Volumes 16, 17, 18, 19, and 20, and of the German Volumes 18, 19, and 20. These will be sent in clean, new numbers, each volume by itself, with index complete, and be forwarded *post paid*. The whole five can be taken together, or one or more copies of any particular volume be selected, as desired. They will be presented as in the table above, viz: For **16** Subscribers at $1 each, (or **30** at 80 cents each,) we will present **five volumes.**—For **13** Subscribers at $1 each, or **26** at 80 cents each, **four volumes.**—For **10** Subscribers at $1 each, (or **20** at 80 cents each,) **three volumes.**—For **15** Subscribers at 80 cents each, **two volumes.**—For **10** Subscribers at 80 cents each, **one volume.**—Let every one selecting these premiums be careful to name just *which* back volumes are desired.

Premium No. 18—Paints.

30 Subscribers at 80 cents each, will entitle the person getting up the club to an assortment of *Windsor & Newton's* **Water Color Paints**—consisting of 12 colors, put up in a neat mahogany case, with brushes, etc. These Paints are imported from London, and are by all considered the best in the world. They are adapted to the finest work, or they will make a neat and appropriate present to any of our younger readers. They will be sent post-paid any where within 3000 miles. (If to go to the British Provinces or to the Pacific Coast, the recipient will need to send 84 cents for extra postage above the 6 cents per ounce which we pay.)

Premium No. 19—Paints.

15 Subscribers at 80 cents each, will entitle the person getting up the club to an Assortment of *Osborne & Hodgkinson's* **Water Color Paints**, consisting of 24 colors or shades, put up in a mahogany case with brushes, cups, etc. These are of American manufacture, and though not so fine as the above, they will answer for ordinary practice by children or beginners, and for common sketching. They will also be sent by mail, post-paid. (If to go to the British Provinces, or to the Pacific Coast, $1.05 will need to be sent by the recipient to pay the extra postage above 6 cents per ounce.)

Premium No. 20—Corn Sheller.

21 Subscribers at $1 each, (or **40** at 80 cents each,) will entitle the person getting up the club to one of the best **$6½ Hand Corn Shellers.** This is a convenient, useful implement, very frequently called for. We give the best implement to be obtained for the price.

Premium No. 21—Hay Cutter.

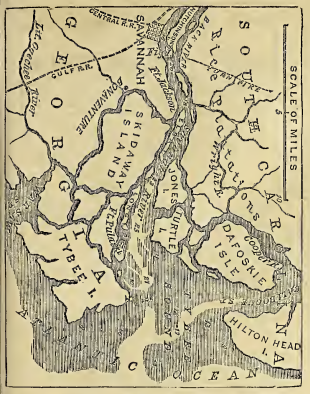
24 Subscribers at $1 each, (or **48** at 80 cents each,) will entitle the person getting up the club to one of the best **$8 Straw and Hay Cutters.** This is a useful implement, needed wherever horses and cows are kept.

Premium No. 22—Subsoil Plow.

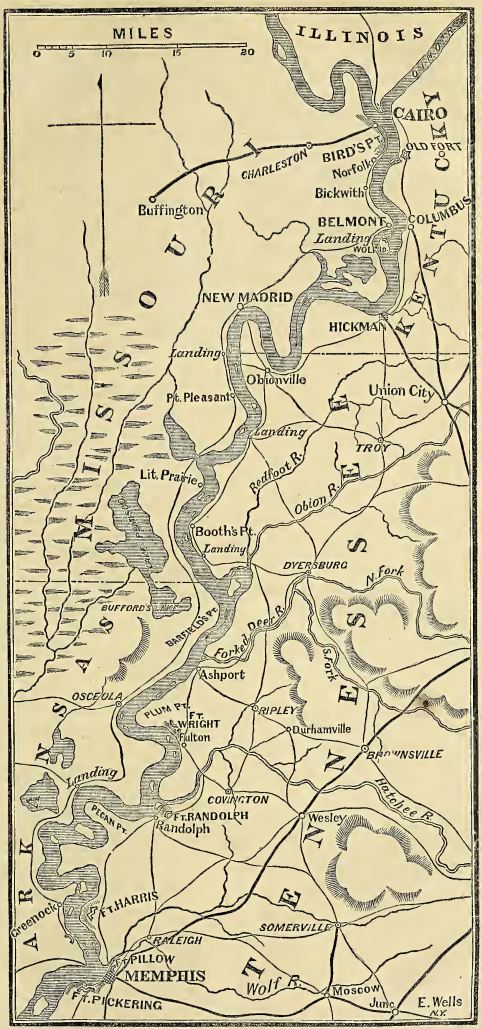
24 Subscribers at $1 each, (or **48** at 80 cents each,) will entitle the person getting up the club to the best **$8 Subsoil Plow** (two-horse), a very desirable implement

Premium No. 23—Good Books.

Here is an opportunity to get a good library at little expense. Any person getting up a club of **16** or more names may choose any desired Books from the list advertised on page 30, *to the amount of* 12½ *cents for each name sent at* 80 *cents*, (or 83½ cents for each name sent at $1); the books will be *delivered to the recipient free of all expense for postage.*



THE MAPS.—In the November *Agriculturist*, we gave 3 re maps, embracing Missouri, Kentucky, part of Tennessee, l the Potomac River from Harper's Ferry to its mouth, with adjacent territory. The extraordinary call for extra copies that number, from subscribers who purchased them for their ends, leads us to conclude that the accompanying maps of nts of present interest will be very acceptable.—**No. 1,** shows location of SHIP ISLAND, which has just been occupied the Union troops as a base of operations in the South West. w-Orleans and its surroundings, and the mouths of the Missis- pi, etc., are also laid down. The small figures on this Map in- ate the depth of water.—**No. 2,** shows another interesting ality, including a part of Hilton Head Island, which exteuds rth to Port Royal and contains Fort Walker, the head quar- s of Gen. Sherman. Tybee Island, Fort Pulaski, Savannah, ., are also seen. **No. 3,** is a locality towards which general ention is directed, and we shall doubtless soon hear of mil- ry operations in that vicinity.—**No. 4,** shows a portion of the ssissippi River, which is just now *the* great center of interest, view of the extensive military preparations, apparently for a scent upon Columbus, by the Union forces, gunboats, etc., w collecting at Cairo, St. Louis, and in various parts of Ken- cky. These Maps, in connection with those given in Novem-



No. 4.—Mississippi River from Cairo to Memphis.

ber, will enable our readers to follow the contending armies in their more immediate operations. Other points of interest will doubtless soon be developed. ☞ We can not longer supply the November number free to new subscribers. Copies can be had at the regular rates (10 cents each).

Advertisements.

Advertisements to be sure of insertion must be received at latest by the 15th of the preceding month.

TERMS—(invariably cash before insertion):

FOR THE ENGLISH EDITION ONLY.

Fifty cents per line of *space* for each insertion.
One whole column (115 lines), or more, $60 per column.

PERIODICALS OF THE AMERICAN SUNDAY-SCHOOL UNION,
No. 1122 Chestnut-st., PHILADELPHIA.
THE
Sunday School World

A Periodical, 16 pp., 8to, for Teachers, Parents, and all who are engaged or interested in the religious training of the young, is published on the
FIRST WEDNESDAY
of every month, and embraces the interests of Sunday-Schools, Bible-Classes, Family Instruction at HOME and ABROAD.

It contains a general survey of the Missionary field occupied by the AMERICAN SUNDAY-SCHOOL UNION and kindred societies in the United States and in other parts of Christendom.

It presents a summary of Sunday-school intelligence from all sources within reach, and a view of the progress and prospects of religious education generally.

Single copies	$0 50 a year.
Five copies to one address	2 40 "
Ten copies	4 50 "
Twenty copies	8 00 "

The Child's World,
A NEW, CHEAP, ILLUSTRATED PAPER,
FOR
CHILDREN AND YOUTH.
WILL BE PUBLISHED BY
THE AMERICAN SUNDAY-SCHOOL UNION,
JANUARY 1, 1862.

"THE CHILD'S WORLD," a paper intended to furnish the children and youth of the United States with reading matter for the improvement of the mind and heart, carefully prepared and illustrated with engravings. It will be conducted in accordance with the principles and objects of the Society, inculcating virtuous habits and instilling the truths of our divine religion. Each number will contain one page devoted specially to the ages and capacities of the very little ones.

"THE CHILD'S WORLD" will be issued semi-monthly, and will be the successor of the *Sunday School Journal*, heretofore published by the Society. The first number of "THE CHILD'S WORLD" will be issued on the 1st of January, and regularly as a MONTHLY, for those who do not wish to take the paper twice a month. The terms for the "CHILD'S WORLD" will be as follows:

Subscribers in a Club,	*Semi-Monthly.*		*Monthly*
10 Copies, per year	$1 50	10 Copies, per year	$1 00
15 Copies, per year	2 20	15 Copies, per year	2 40
20 Copies, per year	2 80	20 Copies, per year	3 75
50 Copies, per year	6 50	50 Copies, per year	7 00
75 Copies, per year	9 75	75 Copies, per year	10 50
100 Copies, per year	13 00	100 Copies, per year	12 00

Subscribers, at their own residences.	*Semi-Monthly.*	*Monthly.*
10 Copies, per year	$1 75	$1 20
15 Copies, per year	2 60	2 40
25 Copies, per year	4 25	3 60
50 Copies, per year	8 50	7 20
75 Copies, per year	12 75	10 80
100 Copies, per year	17 00	14 40

An edition of the Monthly will also be printed on superior paper at the following rates:

By mail, postage pre-paid.	
10 Copies, per year	$1 60
15 Copies, per year	2 40
20 Copies, per year	3 20
100 Copies, per year	16 00

15 Copies, per year	$2 00
20 Copies, per year	2 60
100 Copies, per year	11 00

No club subscription to other edition will be received for a less number than 10. For any number more than 10 and less than 15, the 10 rate is charged, and so on.

For any number more than 15 single rate is charged, 12 cents for the Monthly, and 25 cents for the Semi-Monthly. Subscriptions for a less period than a year will be received at proportionate rates. When furnished at the club rate, they must all be sent to one Post-office.

Payment invariably in advance.

Specimen copies furnished gratuitously on (post-paid) application to any of the Depositories.

PHILADELPHIA, No. 1122 CHESTNUT STREET.
NEW-YORK, 10 Bible House.
BOSTON, 141 WASHINGTON STREET.

Sample copies will be furnished and subscriptions received also by George Crosby, 41 West Fourth-street, Cincinnati, Ohio; Tomlinson Brothers, 128 and 125 Lake-street, Chicago, Illinois; J. W. McIntyre, 9 South Fifth-street, St. Louis, Missouri; and by the Depositories in Louisville, Ky.

PRACTICAL MACHINISTS,
and builders of their celebrated

PORTABLE STEAM ENGINES,
Eaton, Madison Co., N. Y.

These Machines are suitable for giving Power in any place on the Farm, or in Mills, Shops, Factories, Printing Offices, etc. We warrant them to be of Power that we advertise, and to give unqualified satisfaction in every respect of workmanship.

THOS. N. MCCORKEY, of Bayou Boeuf, La., writes in reference to his Engine, in which he says:

"I received my Portable Steam Power Engine, and it is now running to my entire satisfaction. It is so simple in construction that without the assistance of an engineer, I put the engine all together, (as it was all disconnected from the holler,) reversed the motion, etc., although I profess to be no mechanic."

Parties can order Engines direct from our works, which will receive my prompt attention.

Address as above for Circular.

TO THE PATRONS OF
KETCHUM AND HOWARD'S MOWER and Mower and Reaper.

As there have been many inquiries as to the right I have to use the invention, patented to A. W. Morse, of an adjustable Lever, by which the finger bar and knives of a grass harvester are elevated or depressed, I hereby give notice that I have settled in full with said Morse for the use of said invention on *all machines of my* make, and all who have them, are relieved from any liability to said Morse, or his agents, and I have also leased the right to use in future the said improvements, as the subjoined certificate will show.

R. L. HOWARD, Manufacturer, Buffalo, N. Y.

I, Albert W. Morse, the Patentee of the Lifter arrangement for Grass Harvester, do certify, that Rufus L. Howard, of Buffalo, has settled with me for the past, and taken a license for the future, as stated in his card above.

Dec. 15th, 1861. ALBERT W. MORSE.

Ingersoll's Cheap Hand Power Presses for Baling

EXCELSIOR

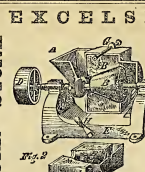

Fig. 2

AND
ANTI-FRICTION
HORSE POWER.

These machines took TEN FIRST PREMIUMS at WESTERN STATE FAIRS last year, and are justly considered superior to all others.

The grinding surfaces of this Mill are BURR STONE, of coarse, fine, or medium cut, as may be required, for fine flour or meal, and the coarsest feed may be ground with the same Mill. Any person can operate and keep the mill in perfect grinding order without expense, and it

WILL LAST A LIFE TIME.

Driven by Horse Power, our *smallest Mill* (No. 1) will grind from 12 to 15 *bushels of feed* the hour; if run by Water or Steam power, 20 to 25 *bushels*. Price of No. 1 MILL FOR FARM use, $100. Nos. 2 and 3, Mills for Miller's use, $140 and $170. The undersigned also make a *Wire Rat Set* for No. 1 Mill, with which Farmers living at a distance from milling establishments are enabled to make their own flour. Price $50 extra.

THE HORSE POWER

FOR DRIVING THRESHING MACHINES, FARM MILLS, HAY CUTTERS, COTTON GINS, CIRCULAR SAWS, MOULDING AND PLANING MACHINES, LATHES, ETC.

Has proved itself to be THE BEST ever invented. The friction is reduced by IRON BALLS, so arranged in all the bearings, that the whole weight of the castings runs upon them. THESE BALLS REVOLVE at the end of a ten feet lever, will keep the power in motion! this permitting the *entire strength* of the horses to be used on the machine to be driven. *One horse* will do as much work on this power as *two* on the Endless Chain Power. IT IS PORTABLE and may be used IN THE FIELD as well as in the house. More than TWENTY FIVE PER CENT of horse flesh is saved, over ANY OTHER POWER IN USE. It is simple in construction, and not liable to get out of order. The $75 Power will drive any Threshing Machine.

Price of Power for 1 to 4 horses $125
Price of Power for 5 to 8 horses 175

Agents wanted in every county. Rights for sale.
Send stamp for Illustrated Circulars to
BEST BROTHERS,
42 and 44 Greene-st., New-York.

A Slight Cold, Cough, Hoarseness, or Sore Throat, which might be checked with simple remedy, if neglected, often terminates seriously. Few are aware of the importance of stopping a Cough or Slight Cold in its first stage; that which in the beginning would yield to a mild remedy, if not attended to, soon attacks the lungs.

Brown's Bronchial Troches were first introduced eleven years ago. It has been proved that they are the best article before the public for Coughs, Colds, Bronchitis, Asthma, Catarrh, the Hacking Cough in Consumption, and numerous affections of the Throat, giving immediate relief.

Public Speakers and Singers, will find them effectual for clearing and strengthening the voice.

Sold by all Druggists and Dealers in Medicine, at 25 cents per box.

GENUINE
SUPER-PHOSPHATE OF LIME,

Manufactured from **Raw Bones**, dissolved in *Sulphuric Acid*, with all the important additions, at $60 *per ton*, by
A. LISTER & BROTHER, TARRYTOWN, N.Y.
(For results of the present season see *American Agriculturist*, for August, 1861, page 252.)

We guarantee every ton of our manufactures to be of uniform quality, and invite trials or chemical analysis.

We also manufacture from RAW, (OR UNBURNED), BONES, the fine, medium, and coarse ground **Bone Manure**, for lasting as well as immediate effect upon all kinds of farm crops. The coarse ground is particularly valuable for *Fruit Trees* and *Grape Vines*, which require a constant and lasting source of nourishment.

For sale in large and small quantities by
A. LISTER & BROTHER, Tarrytown N. Y.
and their agent, F. LANGMAN, 159 Water-st., New York.

100,000 BARRELS
OF THE
LODI MANUFACTURING COMPANY'S
POUDRETTE,
FOR SALE BY
JAMES T. FOSTER,
No. 66 Cortlandt-st., New-York.

The large facilities which they enjoy by exclusive contract for all the night soil of the City of New-York, and large capital invested in their extensive works, enable them to manufacture an article which is superior to any other fertilizer in market, taking *cost and yield* into consideration. It will be sold at the usual price of $2 per barrel for seven barrels or over, delivered free in New-York City.

Please take notice that the office and sale of this Company's Poudrette is changed from Messrs. Griffing, Brother & Co., No. 60 Cortlandt-st., to No. 66 CORTLANDT-ST.

Other brands of what purports to be Poudrette are in market, put up in barrels to resemble this. Beware of frauds—buy that only which has the brand of the Lodi Manufacturing Co. Any other article is comparatively worthless.

We call the attention to the following experiences of practical farmers, in different sections of the country:

NORTH PEMBROKE, Mass., Oct. 7, 1861.

James R. Dey, Esq., President of the Lodi Manufacturing Co.:

Dear Sir—The early autumnal frosts for several years past have seriously injured our corn crop, and rendered it necessary for farmers in this section to seek some fertilizer to give their crops an early start, in order to bring them to maturity in season to avoid that calamity. Having experimented with Guano, Superphosphate of Lime, etc., with indifferent success, in the Spring of 1860 I purchased four barrels of the Lodi Manufacturing Co.'s Poudrette, which I applied principally to my corn crop, with the most satisfactory results. This was the first Poudrette ever introduced into this vicinity. Last Spring I purchased seven more barrels of Boston about thirty barrels, the most of which I sold to my neighbors, who had witnessed the effect of my last year's trial, which, so far as has been heard from, has given entire satisfaction, and will tend to test the efficacy of your Poudrette, this season I ploughed about two acres of light sandy soil, which had laid in grass about six years, (the last crop of grass being very light.) This I planted with corn and potatoes, applying about one tour and a half barrels of Poudrette, with no other manure, except a handful or ashes to each hill at the first hoeing, and the present appearances we shall have a better crop than on a field of like soil where we applied twenty-five loads of manure to the acre. Its effects on garden vegetables are equally apparent. I am, very respectfully yours,
HORACE COLEMORE.

MERRILL, Me., Oct. 11, 1861.

Lodi Manufacturing Co.:

Sirs—I bought of your agents, Cross & Newell, two barrels of your Poudrette, and in the first part, I got about a load and solid the other barrel. But the one that I used I tried the principal part on potatoes. I used about half a pint to the hill, and the yield was equal to those planted on manure at the rate of twenty loads to the acre. My neighbor, who bought the other barrel, says if he had bought five barrels more, he would have saved the price of twenty barrels.
Yours, &c., Y. R. PAUL.

WALDO, Me., Oct. 12, 1861.

To the Lodi Manufacturing Co.:

Gentlemen—Last Spring I bought of Cross and Newell one barrel of your Poudrette as an experiment, but with very little faith in its utility. I put it on six rows of corn in different parts of the field, after ploughing with about 60 lbs. manure, in the usual way—at the second time hoeing. Where I put the Poudrette the corn was twice as large as the rest of the field, and this now is one-third heavier, and has ripened about eight days earlier. I think it the very thing we want for raising corn in this country, and shall use it more extensively another year.
Yours, &c., WELLINGTON SHOREY.

SMYRNA, Del., Oct. 1, 1861.

Gentlemen—I had heard of the Poudrette manufactured by the Lodi Manufacturing Co., and thought I would try a small quantity on a lot of land intended for corn, and as I could not get it nearer than Philadelphia, I went and bought of the agent twenty barrels, and applied two barrels to the acre, dropped the corn and put a handful of Poudrette in each hill. I left out a part of two rows, and put no Poudrette, to ascertain if there was any value in it, and noticed those two rows during the season, and where the Poudrette was used, the corn was decidedly the best, and I have no hesitancy in saying it is a good manure for corn. I am certain I made from one-third to one-half more by using it.
Yours, respectfully, JOHN G. BLACK.

CHESTER, Pa., Sept. 15, 1861.

To the Lodi Manufacturing Co.:

Gentlemen—I purchased the season of Messrs. Baker & Co., eleven barrels of Poudrette and one bag of Phuine, which I put on my corn. I marked the place where I put the Phuine, which, when started, seemed ahead, but now the corn where the Poudrette was put is much the best. Last year I used Allen & Needle's new Fertilizer, which did no good at all, as the corn done better without the manure. I think the Poudrette made by your Company the cheapest manure in use.
Yours, &c.,
A. R. PERKINS.

The Company's pamphlet, containing directions for its use, with other valuable information and the experience of over one hundred farmers, will be sent free to any one applying for the same. Address,

JAMES T. FOSTER,
Care of Lodi Manufacturing Company,
66 Cortlandt-st., N. Y

Publisher's Notices.

Don't Send any more Money by Express.

Owing to a combination among the express companies, and the heavy charges made for bringing money (averaging about 10 per cent on what we have lately received in this way) we must request our friends to hereafter choose some other mode of remitting. The mails are safe if a letter be securely closed and plainly directed. The Post Master General's last report showed that nearly ninety nine out of a hundred of the money letters received at the Dead Letter Office, were astray for want of carefulness on the part of the writers. In the past year we have received as many as a hundred letters containing money, *which had never been sealed at all*, and yet they came through safely. Many other letters have been defective otherwise, owing to the oversight of the writers.

The *best* way to remit money (if $10 and over) is in the form of drafts on a New-York Bank, payable to the order of the publisher. They can now be obtained cheaply at most larger towns, or wherever there is a Bank. Such remittances are absolutely safe, if drawn by a responsible Bank, or Banker. The new Demand Treasury Notes of $5, and $10 or upwards are convenient for remitting. The general currency of the country, however, is now on so sound a basis that bank bills in most of the States are within one or two per cent of par here. Missouri Banks are just now an exception, being 20 per cent discount.

Good Things Easily Obtained.

We again remind our readers that it will be an easy matter for many persons to each obtain one or more good articles offered in our premium list (page 27); they are all desirable. It would benefit us, and be a convenience to other subscribers, if some one at every Post Office would gather up a large number of names and forward. The more subscribers there are in any place the greater will be the improvements made in that locality. Every man set to *thinking* by the hints and suggestions given in this or other journals, will be also set to improving, and his experience and example will be a benefit to others within the circle of his influence.——Will the reader please look over the premium list, and commence a club at once, if some one else is not already successfully engaged in such an enterprise? More than two thousand persons received one or more of our premium articles last year. Over 800 secured the large dictionaries alone, while great numbers obtained the splendid Cyclopedia, Sewing Machines, Melodeons, etc., and we have yet to hear of one who does not feel paid for the effort required.

Flourishing.

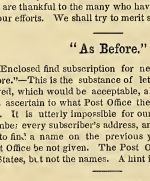
The numerous friends of the *Agriculturist* will doubtless be glad to learn that, despite the war and hard times, the paper is receiving quite as many subscribers as in any former year. We have tried to *deserve* this success, and are thankful to the many who have kindly appreciated our efforts. We shall try to merit still greater favors.

"As Before."

"Enclosed find subscription for next year. Send as before."—This is the substance of letters frequently received, which would be acceptable, always, if we could only ascertain to what Post Office the "as before" refers. It is utterly impossible for our entry clerks to remember every subscriber's address, and next to impossible to find a name on the previous year's book, if the Post Office be not given. The Post Offices are indexed by States, but not the names. A hint is sufficient.

It will Pay.

Our arrangements are such for the present year, that we *know* the *Agriculturist* will be worth vastly more than its subscription price, to every one who reads it. This number, as *full* as it is, is only a beginning. The reader, of course, knows all about this, but there are many who do not. A word to them from a mutual friend (yourself) might be for their benefit——and ours, too.



Can at any time be increased, by remitting for each addition, the price paid by the original members—provided the subscriptions all date back to the same starting point. The back numbers will of course be sent to added names.

Bound Volumes—Binding—Covers.

We have complete sets of Vols. 16, 17, 18, 19, and 20, both unbound and bound separately in neat covers, with gilt lettered backs.

PRICES AT THE OFFICE.

Volumes 16, 17, 18, 19, and 20, *unbound*.....$1.00 each.
Volumes 16, 17, 18, 19, and 20, *bound*.....$1.50 each.
Two consecutive Volumes bound in one cover.....$2.00

PRICES WHEN SENT POST-PAID BY MAIL.

(*They can not go unpaid.*)

Volumes 16, 17, 18, 19, or 20, *unbound*.....$1.13 each.
Volumes 16, 17, 18, 19, or 20, *bound*.....2.00 each.
Two consecutive Volumes bound together.....3.25

BINDING.—Sets of numbers brought to the office will be bound up neatly in our regular style of binding the *Agriculturist* for 50 cents per volume.

PREPARED COVERS.—Covers for binding, neatly made, with title, etc., gilt upon the back, ready for the inserting of the sheets by any bookbinder, can be furnished for Vols. 12, to 20 inclusive, at 25 cents per cover. *Covers can not go by mail.*

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, &c., &c., and to HOUSEHOLD LABORS. It has also an interesting and instructive department for CHILDREN and YOUTH.

A full CALENDAR OF OPERATIONS every month.

THERE'S TO FOUR HUNDRED, or more, illustrative ENGRAVINGS appear in each volume.

Over TWELVE HUNDRED PLAIN, PRACTICAL, in structive articles and useful items, are given every year.

The Editors and Contributors are all PRACTICAL WORKING MEN.

The teachings of the AGRICULTURIST *are confined to no State or Territory, but are adapted to the wants of all sections of the country—it is, as its name indicates, for the whole* AMERICAN CONTINENT.

A **German edition** is published, of the same size and price as the English, and containing all of its reading matter, and its numerous illustrative engravings.

TERMS—IN VARIABLY IN ADVANCE.

One copy, one year.....$1 00
Six copies, one year.....5 00
Ten or more copies one year.....**80** cents each.

☞ Add to the above rates: Postage to Canada 6 cents; to England and France, 24 cents; to Germany, 36 cents.

Postage anywhere in the United States and Territories must be paid by the subscriber, and is *only six cents a year*, if paid in advance at the office where received.

All business and other communications should be addressed to the Editor and Proprietor,

ORANGE JUDD, 41 Park-Row, New York City.

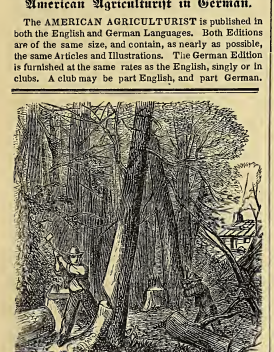
American Agriculturist in German.

The AMERICAN AGRICULTURIST is published in both the English and German Languages. Both Editions are of the same size, and contain, as nearly as possible, the same Articles and Illustrations. The German Edition is furnished at the same rates as the English, singly or in clubs. A club may be part English, and part German.



February.

"Where now the vital energy that moved,
While Summer was, the pure and subtle lymph
Through the imperceptible meandering veins
Of leaf and flower? It sleeps; and the icy touch
Of unprolific Winter has impressed
A cold stagnation on the intestine tide.
But let the months go round, a few short months,
And all shall be restored. These naked shoots,
Barren as lances, among which the wind
Makes wintry music, sighing as it goes,
Shall put their graceful foliage on again,
And, more aspiring, and with ampler spread,
Shall boast new charms, and more than they have lost."

The "cold stagnation" of which Cowper thus speaks, is every where manifest. All the plants are taking their winter sleep, from the tallest trees in the forest to the humblest mosses and lichens that flourish in their shade. For nearly half the year they are as torpid as if they were dead. If there is any movement of the vital forces within, it is carefully concealed. The leaves have fallen from the larger trees and shrubs, forming a warm covering for the delicate plants that flourish only in the protection of the forest. Then the snow falls and makes a still further protection, so that the ground in the far north is often frozen no more than in our own latitude; if the snow comes early, it may not be frozen at all in the deep woods, even in the coldest seasons. If we should remove the snow we would find the winter-green, and prince's pine, the adder's tongue with its purple hues, and its kindred plant the creeping goodyera with its white veined and netted leaves, and the twinberry with its bright scarlet hues, and a great variety of other humble plants as fresh as in summer. Most men are strangers to the world of beauty that lives and has its being under forest leaves, or but just above them. It is one of the advantages of the passion for Wardian cases, which has recently come over our cities and villages that it is bringing to light these lowly dwellers of the retired woods, and secluded swamps. A man may live a life time in the country, and be familiar with the woods without suspecting that there is more than one kind of moss, or of ferns, or of lichens. The mosses have a certain family likeness, but a very slight examination shows as great a variety among them, as among oaks. On almost any dozen acres of our moist woodlands, especially if they are threaded by small rocky streams you may find at least a dozen varieties of the mosses, and as many lichens, with several kinds of ferns. All but the ferns are quite accessible in every mild spell in the winter when the snow and ice melt. Nothing can exceed the delicacy and beauty of some of these mosses. Some are soft and fine as velvet, others of feathery shape, and others still, resemble chased silver. Sometimes the lichens and mosses are found intermingled in the same mass, the lichens sprouting out of the velvet sod like stag horns. The ferns are only to be found by the fallen leaves and stalks of the last season's growth. Nothing can be more charming for the winter parlor than one of these Wardian cases tastefully arranged. Hyacinths and crocuses flourish under the glass, but are not essential to its beauty. Almost all plants like those we have mentioned, which grow in the shade, will do well in the Wardian case.

While the plants are taking their winter rest we may stop to discuss the bearing of labor upon our prosperity. Adam Smith has well said, "Labor was the first price, the original purchase money, that was paid for all things. It was not by gold, or by silver, but by labor that all the wealth of the world was purchased." The land now divided into farms and owned in fee simple was almost worthless to the aborigines, who drew from it a scanty, precarious subsistence, by a very rude husbandry. They laid up few stores of grain, and were always in peril of starvation. It took thousands of acres to support a single individual. This land has become valuable by the *labor* that has been bestowed upon it. Our government assumes that its lands are without value, and it surveys them, and gives a title deed with the guarrantee of protection for one dollar and a quarter an acre, assuming that will be the cost of its survey and protection. The land grows valuable to us, just as we bestow skill and labor upon it, up to a certain limit

The wild land is made valuable to the purchaser, when he puts a fence around it. He may then turn in his cattle and exclude those of his neighbor. If he fells the forest, that labor increases the value of the land by enabling it to yield more grass and hay. He can keep more stock and make more butter and cheese for market. If he plow, after the forest stumps are rotted away, he adds another value to the land by making it yield the roots and grains. He can keep still more stock and get a still larger income from his land. If he lay out still more labor and plow an inch or two deeper, he gets still larger crops and puts a higher value upon the land. We get a very fair crop in some parts of the country if the seed is only dropped and covered upon the plowed land. It is improved with once cultivating and hoeing. But some find that a crop of corn pays abundantly for four times cultivating. Not a weed is left to draw upon the strength of the soil, or to scatter its seed and make work for another season. The more stirring of the soil, they say, the more corn. The more labor the more profit.

Then again, if we add to the plowing and tillage the labor of making and applying manure to the land it is found to pay better still. Just how much we may profitably spend in this way no skillful farmer would find it easy to say; it is much beyond any thing now done. Some acres produce twenty bushels of corn, others eighty. The principal difference is in the labor and manure which is only labor in another form. The fœces of twenty cows for a year occupy but a small space and will be mainly wasted without care. With labor enough they will make two hundred cords of manure. Apply fifty cords of manure to an acre and it yields astonishing crops, so that all the measures and scales are suspected of lying by farmers of the old school, who are afraid of hiring too much labor. The garden has more labor and manure than the field, and so produces vastly more per acre.

It would not do to lay down as a maxim without qualification, "the more labor the more profit," there must be a limit; but it is far beyond our present practice. It is found to be far more *profitable* to raise eighty bushels of corn to the acre than forty, or any less number, in the sea-board States where corn is high. One man works two hundred acres with a single hired man and boy, and just gets a living. Another, with no more capital, works the same sized farm with eight men, the year round, with teams to match, and gets rich. He pays the men from the products of their own labor, and saves a profit to himself. His practice furnishes the needed hints as to the direction in which labor should be employed. In our arrangements for the coming season, we need a more generous faith in the capacities of the soil to reward labor.

Calendar of Operations for Feb., 1862.

[A glance over a table like the following will generally call to mind some piece of work that would otherwise be forgotten or neglected. The remarks are more especially adapted to places between 38° 40' and 45°, but will be equally applicable further North and South, by allowing for latitude. —The calendar will, of course, be much more full during the season of active field and garden work.]

Farm.

This month and the following are the most critical for all kinds of domestic animals, and the stock farmer has enough to occupy his time even though winter reigns in full rigor through the whole of February. The long evenings invite to sociability and neighborly intercourse, and the approaching summer campaign affords a topic for discussion among farmers when they meet. February is the month of all others for Farmers' Clubs to be most useful and attractive. There are grafts and seeds to exchange, and we are beginning the year with the business of 1861 well settled, and out of mind.

Buildings—Keep water out of foundation walls, and thus protect them against the effects of frost, and be always guarded against high winds and sudden changes.

Cattle need a change of diet; manage to let them have it. Look to their comfort most carefully. Cows coming in must be dried off certainly one or two weeks before the new milk springs: feed them generously, not with heating food; roots should form part of their diet. Working cattle ought to have a respite from hard work now if possible, so as to be ready for the labors of the spring; let them lay on a little fat, and keep the skins of all neat stock healthy by currying. Look out for lice, especially on young stock. Do not hold on to beef cattle after they can be sold at a fair price.

Cellars—Look well to the vegetables and remove all decaying ones, "sprouting" the potatoes if necessary. Do not feed decayed cabbages or turnips to milch cows, it will surely flavor the milk.

Corn land of the last season may be cleared of the stubble or stalks while the ground is frozen; at least break off the stubble close to the ground to facilitate plowing.

Drains and ditches—Clear surface drains of ice and other obstructions. See that when the snow thaws, the overflow from drains or ditches does not wash the soil away; and prevent surface water working holes down to the tiles in newly laid tile drains. Protect the outlets from rats and mice.

Fencing—Follow advice given last month and plan for dispensing with as much as you can; have as little as possible, but have it all good.

Fields of grain and grass are invariably injured by cattle and sheep ranging over them in winter, and the temptation to allow it is strongest during February.

Grain—See Calendar for January.

Hired Men—Farm hands should be engaged early. The best find places soonest.

Horses, and mule teams, must be kept well shod and sharp. If a horse breaks his leg you can't "help" him. Breeding mares should not leave the stable in very icy weather. Devote some time daily to colts of a suitable age for breaking.

Hogs should be kept hard at work upon the manure in barn cellars if possible, otherwise secure them warm quarters and feed them so as to keep them growing and healthy. Do not let the troughs fill up with frozen swill. Breeding sows should be kept separate and have warm retired nests, where they can be easily got at. Feed raw sliced roots occasionally; it prevents constipation and the tendency to devour their young.

Ice—Quick, or it will be gone; it is seldom worth much for storing after the 10th of February.

Manures—Fine composts, with soil, head lands, or muck, well incorporated, may be hauled to the field while the ground is frozen. See that all sorts are well mixed and composted as it accumulates. Keep frost out of the manure heaps if practicable.

Maple Sugar—Prepare to make all possible, and be ready for the first flow of sap—this is the sweetest. See article on page 42.

Potatoes for Seed—Keep where they will not sprout; but do not rub the sprouts off.

Poultry—Whitewash the poultry house and grease the roosts. Change the old nests, and encourage laying by feeding beef scraps or bits of meat from the table.

Sheep must not be allowed to fall off in condition.—They will relish hemlock branches and they are good food for them in limited quantities. Feed breeding ewes a quart of sliced raw potatoes with a very little meal upon them, daily. Never let sheep lack water or salt—and above all, feed regularly.

Tools—Provide a good supply for spring work, while you have means to buy and to select them at leisure.

Orchard and Nursery.

Little can be done in this department until the ground is in order for transplanting. The earlier that can be done, the better. Thousands of trees are yearly destroyed by too early swelling of the buds, which are killed by succeeding frosts. Small trees (as peach trees and apricots) may be protected by pine and hemlock boughs tied in among their branches and by stamping snow down about their roots—applicable only on a small scale.

If trees are frozen after being taken from the ground, bury them tops and all; they will sustain less injury if thawed gradually. Make things ready for spring work.

Cions will soon be needed. Procure only choicest kinds, and in mild days when not frozen. Label each sort distinctly, and keep in sand in the cellar.

Insects of some kinds are more readily destroyed now than later in the season. Scrape trunks and main limbs of trees infested with bark-lice, and scrub with lye.

Manure—Draw out and spread under the trees, at least as far as the branches extend in orchards or level grounds.

Orchards do not need manure every year. Apply unleached ashes or fresh slacked lime when the frost is leaving the soil, not before. Pare trees love ashes.

Pruning—It is best to abstain even from *knife* pruning as we approach the time for sap to start. Many prune now to the great injury of the orchards. Dwarf pears, however, may be pruned without danger.

Snow—Be always watchful in case of snow and ice storms, and support the branches in danger of injury before it is quite thrown down.

Stakes, labels, tallies, packing bags, mats, etc.—Be sure to have prepared, before hand, all that you will need for spring use during the season of nursery planting or sales.

Varieties to plant or graft—Give up old fogy notions, and study well and adopt the best varieties of all kinds of fruit and ornamental trees. A nurseryman who gets behind hand stays behind hand in this respect.

Kitchen and Fruit Garden.

Every thing that may in the least forward spring work in the kitchen or market garden, should be done, and as the busy time approaches many things will occur to the mind which should be made a note of. No novice should attempt very early forcing vegetables for market, but to succeed well, he should grow into the practice after a year or two, beginning a little earlier each year.

Cold Frames—Admit air during mild weather, and watch against dampness and decay. Guard against sudden freezing. Spread over them mats or straw, when unprotected by a covering of snow.

Cuttings of Currants, Gooseberries, etc., may be made whenever the wood is not frozen, but better in the Fall.

Fences—Repair old, and make all hen proof. Provide proper fastenings for gates.

Grape Vines—Prune at once, if not done in the Fall.

Manure—A garden can hardly have too much; it should be finely divided and intimately mixed with the soil. For fruit trees, leaves, or sawdust saturated with urine is an excellent application. For the garden rich composts of all kinds, particularly night soil, hen dung, etc., with fine yard manure and muck, are excellent.

Prune Currants and Gooseberries and clean out the old stalks from Raspberries if neglected until now; cuttings of the two former will grow if kept till spring.

Rhubarb in open ground can be hastened by covering with horse manure now, later with a headless barrel.

Seeds—Examine the list for free distribution from this office, printed on a subsequent page, and select new or favorite kinds. Procure and study catalogues of reliable seedsmen whose advertisements appear in the appropriate department. Test samples before purchasing largely. They are best proved by mixing with a little sandy soil and keeping them in very small pots under a glass.

Stakes—Prepare a good supply and soak them in a weak solution of blue vitriol in water, etc.

Tools—There are always new and improved kinds claiming attention. Put the old stock in good order.

Flower Garden and Lawn.

Do not think there is nothing to do in the flower garden; on the lawn there is in fact little, save to keep an eye to the shrubbery and evergreens, and see that high winds and heavy snow and ice storms do no harm, but in the garden, look to the

Borders—Winds will tear away the protection about many half hardy plants, and it must be replaced. The fowls, if they have the range of the place as usual, will scratch off the mulch over the crocus, hyacinth and tulip beds, perhaps exposing the bulbs even. It does no special harm if the mulch be at once thrown back again.

Christmas greens, when taken down are very handy to give a little additional protection wherever needed.

Cold Frames—Give treatment elsewhere advised.

Cuttings may be taken; prune and trim hardy shrubs.

Frost most commonly does its damage to vegetation in February. The best shield is protection against the morning and midday sun on warm spring like days.

Hot-Beds may be made for seed of early flowers, to hasten their blooming period, and to start cuttings. Many plants will strike in a hot-bed with a moderate heat, which could hardly be made to grow in the open ground.

Roses—Begin pruning in mild weather.

Transplanting and shifting roots of perennials, etc., should be done just as soon as the frost is out of the ground. The earlier the better.

Trellises and Arbors—Provide for vines and trailing plants. Repair all needing it and paint while the ground is covered with snow and no dust is flying.

Green-House.

The directions of last month suffice for this in the main. The great art in managing a green-house is to keep the temperature low but never too low, and to keep down insects. Bring plants beginning to grow or showing for bloom close to the light.

Cuttings of many of the woody plants may now be made and potted. They strike better if taken to hot-house.

Prune into shape any plants needing it, before a new growth begins or flower buds form, and remove all decaying branches, dead leaves, weeds, and moss, keeping every thing neat and clean.

Repotting will claim a full share of the manager's time this month, if the collection is large. Many of the plants may now be carried to the forcing apartments to hasten the blooming period.

Roses—Attend to grafted stock, or graft if not done.

Water—Increase the amount as the plants push into growth, but avoid an excess.

Hot-House and Conservatory.

In the conservatory follow directions given last month. In the hot-house maintain 70° to 80° of heat. If snow falls, the roof should be cleared to admit the light which the rapidly growing plants now require. Air must be given the plants frequently, but much care will be needed to prevent chilling drafts striking directly upon the plants. Maintain a constantly moist air by sprinkling freely.

Annuals—Seeds of many of the out-door annuals may now be sown in pots. They will form good sized plants for decorating the border early in the season.

Azaleas, now in bloom, should be watered freely. Avoid syringing after they are in full bloom.

Bedding Plants—Layer or insert cuttings of Petunias, Pelargoniums, Verbenas, Dianthus, Candytuft, Pansies, Dicentras, Daisies, etc., for early planting in open borders.

Bulbs—The early forcings should now be in bloom, and others in a good degree of forwardness. Bring a fresh collection from the green-house, every two weeks.

Camellias—Look out for red spider; if affected, wash each leaf with a sponge and soft water, and syringe with water containing flour of sulphur.

Insects—Fumigate with tobacco, destroy any which have established themselves, and wash with soap suds.

Repotting—Many rapid growing plants require pots of a larger size. Keep potting soil at all times in readiness.

Grapery and Orchard-House.

Cold graperies and orchard houses will need no more attention than last month, until the weather becomes decidedly warm and spring like, which seldom occurs north of latitude 41°, before March. The vines should then be lifted, and tied to the rafters, and the borders watered with liquid manure. In houses to be brought forward by moderate heat, do the same and maintain a temperature not much above 50°, in the day and ten degrees lower at night. Water sparingly with liquid manure. When growth begins vigorously, follow up with careful pinching-in, and occasional sprinkling. Keep a moist atmosphere particularly on warm days by sprinkling the floors and walls. Compare directions given last month.

Apiary in February.

Prepared by M. Quinby—by request.

There is yet some danger that steady cold weather will close the air passages with frost, dead bees, etc. A day or two of severe weather will not effect much, but when protracted to a week or two, the bees will need attention.

In times of mild weather, sweep out clean under the bees. If the stands of any hives are to be changed, it should be done before the bees fly out and mark their locality. Should they be moved but a short distance, the importance of doing it now, is much more. Have a separate stand for each hive, instead of a long bench for all. You can then give some five or six feet space to each, without vacant room on the plank. If a bee-house is to be used the coming season, it should be ready now to put in the hives. Bee houses can be very ornamental, yet they are not always the most profitable places, in which to keep bees. A bee-house would do very well, even with the hives crowded together as they usually are, if all the new colonies introduced could be provided with a fertile queen, and no swarming allowed, as then there would be but little danger of her issuing to meet with them, and getting destroyed by entering the wrong hive on her return. This process will soon become familiar to those who introduce the Italian bee into their apiaries.

All who intend to Italianize their bees the coming season, should make their preparations now, and not wait until attention to spring work leaves no time to think how it should be done. Any of the movable comb hives are so much superior to the common box, for changing bees from the native to the Italian, that I can not imagine how a person can feel satisfied to be without one. The bees, comb, and honey, can be transferred from the one to the movable frame hive, early in Spring. To rear the queens you must enclose a few bees with a small piece of comb containing young larvæ or eggs. A suitable piece of comb can not be cut from a large sheet without destroying much of the brood, and the few bees generally taken for this purpose, need something much smaller than the ordinary hive. To have the operation work smoothly, you want a special arrangement, something like the following: Get the size of one of the large frames inside; make a number of small frames of just that fit. Have them as near four inches square as the shape and size of the large one will admit. If operations are to begin early, fit a piece of clean worker comb into each small frame. Fasten them into the large frame, with wire, or strips of tin, or something easily removed, as it will often be desirable to take out a large frame and remove a small one without disturbing the bees that happen to be attached. This frame thus prepared is introduced into a colony where there is an Italian queen, a few days before brood is wanted. A miniature hive that will hold three or more of these small frames will be needed. It should be so arranged that it may be easily examined at all times. These little colonies are not so irritable as larger ones, and afford a much better opportunity of studying the most interesting points of natural history. If these boxes are to be painted, it should be some light color, and should be put on immediately, that the odor of new paint may in some measure pass off before using. Particular directions for rearing queens and introducing them, will be given at the proper season.

Exhibition Tables at the Office of the American Agriculturist.

The following have been exhibited since last report:

VEGETABLES.—Chinese Potatoes, 2 years old and fine, grown in sandy loam, by Mr. Downing, Newburg, N. Y. ....Sample of Sorghum, J. N. Carr, Philo, Champaign Co., Ill....Variegated Corn, Mr. Wilson, N. Y.....Collection of Corn, W. S. Carpenter, Rye, N. Y.....Tripsicla Corn, Mr. Wilson.....Collection of Corn, J. M. Thorburn & Co., N. Y.....Improved King Philip Corn, from seed from the *American Agriculturist*, fine, C. E. Wheeler, Bergen, N. J.....Hubbard Squash, weight 17½ lbs., the finest specimen we have seen, B. Williams, West Bloomfield, N. J.....Specimen of Corn, from the same.

FRUITS.—Seedling Winter Pears, very fine, A. M. Halsted, Rye, N. Y.....Collection of Apples, E. Williams, West Bloomfield, N. J.....Newtown Pippin Apples, of 1860, kept remarkably well, somewhat shriveled in the flavor, Robert Benner, Esq., Astoria.....Cider from Iron Apples, (so termed from their hardness), delicious, G. M. Usher, Staten Island, N. Y. ..Collection of Apples, G. M. Usher, as above.

MISCELLANEOUS.—Mole Trap, Micajah T. Johnson, Short Creek, Harrison Co., O.....Collection of Brazilian seeds, Mr. Colvin, N. Y. ....Specimens of Amatito, T. W. R., from Jamaica, W. I.....Seeds, from Geo. Latimer, Esq., St. Johns, Porto Rico, W. I.....Broom Nest, Mr. Faitham, New Utrecht, L. I.....Sorghum Molasses, E. A. Van Meter, Washington, Ill. ....A piece of fine floor which Col. Ellsworth felt, Mr. Frederick, Alexandria, Va.....A Bouquet of skeletonized flowers, leaves, seeds and capsules, in a glass case, one of the most beautiful and natural parlor ornaments extant, W. F. Heins, Woodstock, N. Y. ..Wasps' nest, W. F. Heins, Woodstock, N. Y.....Sorghum Molasses, fine, John Manwaring, Mendota, La Salle Co., Ill.

CURIOSITIES.—Briar, from which briar wood pipes are made, Jas. T. Sample, Allehany City, Pa. Sutler to the Round Head Regiment.....Bark of the Palmetto Tree, brought by Jas. T. Sample, from Port Royal. S. C.

Seeds for Free Distribution to all Subscribers for 1862 (Vol. 21.).

Every subscriber to the Agriculturist for 1862, *is invited to select* **four or five parcels** *of seeds from the list below.*

These seeds are all valuable. Of the **90** kinds offered, many are *new* varieties, but we include some common useful sorts for convenience of those without access to good seeds.

Most of them are annuals (reproducing seed the first season), and in all cases there will be enough to yield a good supply for future use. Our aim is to furnish the germs of future abundance in each locality where these seeds go.

Many of these seeds were grown by ourselves, the past year; the others are obtained of the best growers here and in Europe. The distribution will begin the last of February.

Mode of Distribution.—The seeds may be called for at the office after Feb. 25, or be applied for by mail at any time now, to be forwarded when ready. **The postage is only 4 cent per ounce under 1500 miles; and 2 cents per ounce when over 1500 miles.**

Those sending for seeds to be forwarded by mail, will please *carefully* observe the following

DIRECTIONS.—(1.) Select from the list below, any four or five parcels desired, and write *plainly* on a slip of paper the *numbers* (only) of the kinds of seeds wanted. (These numbers are used on our seed drawers, seed bags, &c.)

(2.) Enclose the slip in a prepaid envelope—directed in full to your own address, as here shown, and put upon it postage stamps to the amount of **one cent** *for each ounce of seeds to be inclosed*, if **to places under 1500 miles, or two cents if over 1500 miles.** Most places West of the Mississippi river are over 1500 miles. The exact total amount of stamps required can be reckoned from the table of rates below. Any fraction over even ounces will require a full 1-cent stamps according to distance. Forward the above prepared envelopes to this office, and the seeds will be carefully packed to the numbers on the enclosed slip. To save letter postage, let there be *no marks on the envelopes* except the address and stamps. (Letters and notices will go by common sized envelope.

John Smith,
Post Office,
Munroe County,
State.

Field, and Vegetable Garden Seeds.

No.		*Weight of package.*
183	—Mammoth Long Bearded Spring Wheat.....One ounce.
2	—Improved King Philip Corn.....One or two ounces.
141	—Darling's Early Sweet Corn.....About one ounce.
142	—Stowell's Evergreen Corn.....About one ounce.
98	—Long Red Mangel Wurzel.....About one ounce.
187	—Comn. Broad Leaf Tobacco.....About one-eighth ounce.
188	—Genuine Havana Tobacco.....About one-eighth ounce.
189	—Sweet Scented Tobacco.....About one-eighth ounce.
180	—Spelt or German Wheat.....About one ounce.
99	—Norbiton Barley.....About one ounce.
	8—Daniel O'Rourke Pea.....About one ounce.
	9—Champion of England Pea.....About one ounce.
	99—Prince Albert Pea.....About one ounce.
	13—Green Edible Pod Pea.....About one ounce.
	13—Enfield Market Cabbage.....About one-fourth ounce.
	14—Flat Dutch (Winter) Cabbage.....About one-fourth ounce.
	193—Improved Stonehouse Cabbage.....About one-fourth ounce.
	199—Red Dutch Cabbage.....About one-fourth ounce.
	15—Early Purple Vienna Turnip Rooted Cabbage.....About one-fourth ounce.
	150—Early Paris Cauliflower.....About one-eighth ounce.
	147—Improved Short Prickly Cabbage Lettuce.....About one-fourth ounce.
	72—Imported Brussels Sprouts.....About one-eighth ounce.
	18—Improved Long Orange Carrot.....About one-fourth ounce.
	148—Long dark Blood Beet.....About one-half ounce.
	149—Early Nutmeg Bassano Beet.....About one-fourth ounce.
	95—Hubbard Squash, pure.....About one-fourth ounce.
	193—Green & Italian Red Tomato.....About one-eighth ounce.
	154—Ice-cream Water Melon.....About one-eighth ounce.
	155—Gilliflower Netted Muskmelon.....About one-eighth ounce.
	194—Hollow Crown Parsnip.....About one-fourth ounce.
	156—Extra Curled Parsley.....About one-fourth ounce.
	151—Yellow Danvers Onion.....About one-fourth ounce.
	152—Fine Large Cheese Pumpkin.....About one-fourth ounce.
	17—Red Strap Leaf Turnip.....About one-fourth ounce.
	71—Long White French Turnip.....About one-half ounce.
	195—Early Scarlet Horn Carrot.....About one-fourth ounce.
	74—Solid White Celery.....About one-fourth ounce.
	75—Sage.....About one-eighth ounce.
	156—Summer Savory.....About one-eighth ounce.
	197—Long Red Mangel Wurzel.....About one ounce.
	196—Green Curled Kale.....About one-fourth ounce.
	198—Improved Large Egg Plant.....About one-eighth ounce.
	21—Winter Cherry.....About one-eighth ounce.
	197—Lima or Sugar Beans.....About one-half ounce.

Flower and Ornatmenal Seeds.

89—Cotton Plant (2 kinds, mixed).....	One-half ounce.
111—Castor Oil Bean	One-half ounce.

On an average any five of the following varieties will go to the ounce, per stamp, (or one cent per ounce.)

200—Fancy Gourds, (mixed varieties) *(ha)*	212—Fine Sweet Peas, *(ha)*
201—Scarlet Chinese Egg Plant, *(ha)*	124—Whitlavia, *(ha)*
202—Diamond Oats, *(ha)*	125—Candytuft, *(ha)*
177—Graceful Quaking Grass, *(ha)*	123—Gilia tricalis, *(ha)*
23—Mignonette, *(ha)*	126—Clarkia elegans, *(ha)*
24—Zinnia, *(ha)*	163—Clarkia pulchella, *(ha)*
31—Chinese Pink, *(ha)*	127—Virginian Stock, *(ha)*
32—Portulacca Mixed, *(ha)*	168—Swan River Daisy, *(ha)*
33—Phlox Drummondii, *(ha)*	128—Mixed Scabiosas, *(ha)*
34—Passel Flower, *(ha)*	40—Eschscholtzia Californica, *(ha)*
35—Nemophila Insignis (Mixed) *(ha)*	213—Xeranthemum Annum *(ha)*
203—Mexican Poppy, *(ha)*	214—Lobed Tubed Centranthus, *(ha)*
204—Red French Poppy, *(ha)*	216—Autumn Roseum, *(hha)*
205—Mixed Annual Larkspur, (mixed colors) *(ha)*	214—Balsam Vine, *(hha)*
183—Fine Mixed German Asters, *(ha)*	37—Cockscomb, *(ha)*
206—Golden Striped Flowering (everlasting) *(ha)*	35—Cypress Vine, *(ha)*
208—Common Globe Amaranth, (everlasting) *(ha)*	207—Rhodanthe Manglesii, (everlasting) *(ha)*
210—Convolvulus Tricolor, *(ha)*	122—Mixed Canterbury Bells, *(hb)*
172—Mixed Larkspur, *(ha)*	125—Standing Cypress, *(hb)*
167—Malope Grandiflora, *(ha)*	42—Foxglove, *(hb)*
211—Fine Mixed Lupins, *(ha)*	209—Dwf Chinese Larkspur, *(hp)*
	171—Forget-Me-not, *(hhp)*
	215—Eccremocarpus Vine, *tp*

* *(ha.)* hardy annual; *(hha.)* half hardy annual; *(ta.)* tender annual: *(hhA.)* half hardy biennial; *(b)* tender biennial; *(hp.)* hardy perennial: *(hhp.)* half hardy perennial; *(tp.)* tender perennial.

Containing a great variety of Items, including many good Hints and Suggestions which we give here in small type and condensed form, for want of space elsewhere.

"All in a Heap."—To Correspondents.

—This being a general time for renewing subscriptions, it very naturally happens that our readers embrace the occasion to send in their favors—articles, items, queries, etc., they come "all in a heap." We have not the slightest fault to find with this—but return thanks for the numerous letters. We simply refer to the same to shield ourselves from any suspicion of want of attention or courtesy, at this our busiest season, if we are less prompt in referring to all letters that come, than might be looked for, without this explanation.

Please Condense.

—To some sixty persons, more or less, who have recently sent in from 5 to 30 pages of manuscript, on a variety of topics, most of them offered for sale, we must say one word. Please *condense* more. We have no time to even read through an article that occupies a page in giving only one idea. There is a single item of not over 20 lines in this (February) number, which contains the *essence* (every useful thought, and hint,) of all that came in a manuscript of nine foolscap pages! There are only 32 pages in each paper, all told, and we desire to condense a great deal into them. A RULE: *Any article designed for publication in the Agriculturist, and containing a certain amount of information, is valuable just in proportion to the smallness of the space it occupies, provided its statements be clear, with all needed particulars to make it complete.*

Our War Maps

appear to have given general gratification, judging from the very numerous references to them in letters received. The contending armies have been nearly quiet since our last—they are apparently gathering up their strength for a terrible conflict, or series of conflicts. We are in doubt as to what point will next come into prominently enough to need illustration, and therefore send this number to press without new maps—having already fully illustrated Missouri, Kentucky, part of Tennessee, Eastern Virginia, Port Royal, Tybee Island, Fernandina, and New-Orleans, in our last three issues.—P. S. As we close up these pages, (Saturday, Jan. 18,) the reports are, that stirring events may be looked for on and near the Eastern coast of North Carolina and Southeastern Virginia, and we will therefore give, on page 36, a map of that region.—**2nd** P. S. *Jan.* 20.—The telegraph reports there has been a great battle at Somerset, Ky., resulting in the defeat and death of Gen. Zollicoffer. Somerset is 85 miles Southeast of Frankfort. This, and all other principal towns in Kentucky and in Northern Tennessee, are fully shown in the *Agriculturist* maps, given in November and January.

Boys on Farms.

—In response to our inquiry in the January *Agriculturist* we have a number of letters from reliable men and excellent farmers. These can be consulted at this Office.

Linnæus Rhubarb Seed Worth Trying.

—As announced in last volume, we have a large quantity of very fine pure seed, gathered by ourselves last Autumn, for our Seed Distribution, (No. 197). The Linnæus is the best variety, and though the seed is not certain to reproduce exactly the same variety, it will be most likely to furnish many plants quite equal to the original. Every family that can not obtain the pure roots, and thus save a year or so in time, should sow the seed. It will be especially valuable at the West, and other points distant from reliable commercial gardens or nurseries. Time will be gained by starting the seed in a hot-bed and transplanting the first of May to a rich garden soil, and pushing the plants forward by occasional waterings with liquid manure. They will afford considerable picking the next year, and only the plants proving best may then be preserved, to be multiplied as desired, by dividing the roots. In the absence of a hot-bed, sow early in the open ground, in a sheltered place. Make the soil very rich with stable manure, and treat as above directed for hot-bed plants.

Death of a Royal Patron of Agriculture and Horticulture.

—Since our last issue, the sad intelligence has come of the death of the Royal Consort of the Queen of England, Prince Albert. While occupying so high a position, he ever justly considered that he could render the greatest service to his people by

fostering in them a love for rural occupations. This he did not by advice alone, but by *example*. His farm, his stock, and his garden, cultivated under his own eye and direction were models to be imitated. He thought it not unbecoming to serve as an active officer in both the Royal or National Agricultural and Horticultural Societies of England. To the Presidency of the former Society he was elected the past year, and he held a similar office in the latter Society for two or three years past. Since his death the Queen has requested that the Horticultural Gardens should be considered under her peculiar and *personal* patronage—a touching mark of respect for her deceased Consort. We are glad to know that prior to his death, Prince Albert exerted his utmost influence to quell the senseless clamor for war with America, and counselled peace with a great agricultural people to whom he was attached by kindred tastes, and national courtesy. We regard with pleasure the banner which was suspended across the street in front of the *Agriculturist* Office, on the occasion of the visit of the Prince of Wales, on which is inscribed, "WELCOME TO THE SON OF ENGLAND'S NOBLEST PATRON OF AGRICULTURE." We had hoped during the coming Summer to in person pay our respects to the father, and examine for ourselves the farm and garden under his supervision. But that can not now be.

Training the Currant.—D. S. Yes, it can be trained, and to good advantage. You may let it grow up into a scrubby bush, with a dozen stems from the ground; but in that case, you must make a desperate effort every other spring, and cut out the old wood. It is preferable to make a miniature tree of each plant, and trim and shape it like a handsome pear-tree. Or, if you want variety, you may train it on a frame or trellis, spreading out, and about three feet high. By the last two methods, you will get larger, handsomer fruit.

Apples from Seed.—H. Grundy, Macoupin Co., Ill. Apple seeds will not produce the same varieties as planted. Seeds from good sorts are most likely to yield good apples.

Dwarf Apple Trees.—The Country Gentleman recommends planting dwarfs on the Doucain stock 8 feet apart, and 6 feet on the still smaller Paradise stock, for garden culture. The latter will yield crops the second, and the former the third year from planting. Among the varieties most suitable for dwarfs are: Red Astrachan, Jersey Sweet, Porter, Baldwin, Dyer, Summer Rose, Benoni, Sweet Bough, Northern Spy, Twenty Ounce, Wagner, Early Strawberry, Fameuse, Canada Red, etc. All the above will need more or less pruning either in the top or side branches to preserve a good shape.

Packing Grapes, Peaches, etc.—An English gardener who sends grapes and other tender fruit long distances, first covers the bottom of the boxes with wheat bran, then a layer of fruit carefully wrapped in soft paper, sifting in bran to fill the crevices, shaking the boxes a little and repeating this until the box is filled. Fruit packed in this way is said to bear long carriage without even losing the "bloom," which is most important as its presence is proof of careful handling.

Winter Pears.—"Central New-York." Winter pears are *not* "a humbug." They often fail, but with proper care, will generally succeed. The fruit should be as well ripened as possible before gathering; therefore let it hang on the tree until just before hard frosts; then pick on a dry day, put in boxes or barrels in a cold cellar, and cover tightly. When the proper period for the ripening of each comes, take them from the cellar and put them in a warm closet, say ranging from 60° to 70°. Keep in the dark, and they will slowly color up and become tender and juicy. As we write, the fine flavor of a Winter Nelis is on our tongue. Among the best sorts, we name: the Lawrence, Winter Nelis, Easter Beurre, Passe Colmar, Beurre d'Aremburg, and Vicar of Winkfield. Beurre d'Anjou ripening in November, is first-rate.

Varieties of Pears for an Orchard.—" Subscriber," in TIOGA Co., N. Y., asks what varieties of standard and dwarf pears we would advise planting for market use, ripening early and late, on 3 acres of land, setting the standards 20 feet apart, with dwarfs between them..... This will take about 325 standards, and about three times as many dwarfs, or 975, planting them between the standards each way, and setting a tree in the centre between each four standards. For the standards we would plant 10 each of Tyson, Madelaine, Beurre Superin and Winter Nelis; 20 each of Rostiezer and Beurre Giffard; 25 Fondante d'Automne; 30 each of Lawrence and Beurre Clairgeau; 58 Flemish Beauty, and 100 Bartlett. For the dwarfs we would take 25 each of Tyson, Kirtland, Doyenne d'Ete, Seckel, Doyenne d'Hiver Noveau, Flemish Beauty, Bartlett, Glout Morceau, Henry IV., Napoleon, and Stevens Genesse; 50 each of Rostiezer, Duchess d'Angouleme, White Doyeane, Beurre Diel, Easter Beurre, Fondante d'Automne, Beurre Superin, Beurre d'Anjou, Vicar of Winkfield and Winter Nelis, and 200 Louise Bonne de Jersey.

Protecting Tender Vegetation.—(A. P.) During this month and the next, see to it that the tender fruit tender trees are carefully protected. Young pear trees, cherries and even apple trees a few years planted, are benefitted by setting up a board on the south side of the trunk, to keep off the sun. Or, if you please, wind a thin band of straw around them. Examine your shrubbery and tender plants, and see if the heavy snows have not broken off their wrappings, or if the dogs, hens or rabbits have not scratched them off. These two months are the most trying of the year to tender vegetation.

Double Flowers.—A correspondent of the *Agriculturist* from Boston, states that from the same parcel of seed he raised stock Gilliflowers, in 1858 almost all double; in 1859 half, and in 1860 two thirds were single. The reason is obvious. It is an excess of vital force exercised in a given direction that makes a double flower—where this excessive vitality is lost, we might expect the flower to be single, and so it is. It is interesting in this connection to note that this loss of vital force which obtains should increase the ability to bear seed.

Poor House-plants.—(Jane.) Your trouble arises from too dry an atmosphere. A coal fire is worse than a wood fire for plants. Suppose you try, next year, a collection of Cactus plants. They are odd if not pretty; and they will stand heat and dryness, without wincing. The Epiphyllums and Cereus sections have magnificent flowers. Try the Aloes. They have quite a tropical look, and only need an occasional sponging. Can't you put a few of your fine plants under glass shades?

Castor Oil Bean.—H. A. Curtis, Portage Co., O., is informed that the Castor Oil is made from the seed, called a *bean* (seed list, III.) produced by this plant. There are certain dwarf varieties for garden and greenhouse culture, which so far as we know, are neither more productive nor earlier than the common kind. The oil is simply expressed and subsequently purified. Probably in Portage Co., O., the culture would not be profitable.

Chickweed.—R. W. Tell your friend that chickweed is an annual plant. It grows from seed every year; so, if he does not let it go to seed, as soon as all the seeds in the ground have sprouted he will be troubled no more. Hoe the ground often in hot dry weather. This will destroy the weed effectually. The culture of root crops and cabbages we would recommend if the ground is suitable and very full of seed.

The Tap Root.—"William." As to whether you should cut it off, will depend upon circumstances. "When nature," observes a writer, "puts a tap-root at the bottom of a tree, or a tail on the *other* end of a pig, she does it for some good purpose, and neither of them should be cut off without a valid reason." As to the pig, we won't debate, but as to trees, we know there are good reasons, at times, for amputating the tap-root. In seedlings standing in nursery rows, the central roots shoot down strong and deep, and must be cut off early, if we ever expect to transplant the trees. It is so with the oak in a remarkable degree. Cut off the tap-root when the tree is small, and a new set of horizontal roots will be formed, with many forks and numberless small roots and spongioles. And then, the transplanting will be easy, and the living quite a sure matter.

To Prevent Suckers.—R. M. S. Keep the soil loose and clean; apply in early spring unleached wood ashes and bone earth; and cut off the suckers with a sharp knife as soon as they appear.

Rape Seed Oil.—Why, asks a German subscriber, is not Rape grown as a field crop in this country, where spring frosts are not very heavy? I do not envy the Pennsylvanians for having discovered the coal oil fountains, for I can not get used to that. I want the pure, clear oil from winter Rape seed, which is without odor, and gives a soft, beautiful light. In Germany many of our large farmers pay their high rents from the sale of rape seed and wool alone.

Keeping Seed Peas from Bugs.—P. Hammer, of Boyd Co., Ky., writes: "Put the peas in bags, and for every quart add two handfuls of fresh wood ashes. Shake the bags well, and keep in a dry place. I have tried this several years, and the peas have always remained as sound and fresh after a year as when first put up, and no bugs or weevils were found in them.' We think they must have been free from bugs when put up, for the eggs from which the bugs hatch, are laid in the peas when growing in the pods. The dry ashes around them would hardly prevent the development of the bugs inside the kernels, where they grow, and come out to multiply usually after the peas are grown.

Cotton Seed—A Caution.—The interest awakened in reference to the culture of cotton in the Southern tier of the Middle States, is already leading to speculation in the seed; and, according to the newspapers, Government has appointed an agent to procure seed at Fort Royal, and distribute it through the West. Large quantities of Sea-Island Cotton are being brought to this City before ginning, (cleaning from the seed,) so that there will be plenty of this kind of seed. But we will remind the readers of the *Agriculturist* that the Sea-Island cotton can not be cultivated, with hope of a crop, away from the sea-board, and there only in particular localities. The "Upland Cotton" as it is called, is the kind to experiment with. The two kinds of seed are very readily distinguished. The Sea-Island seed is nearly black, and has a *smooth, naked shell*, except a small belt of cotton, hardly larger than a pin-head, on the small end—with sometimes a very little on the other end, and along one side. The Upland seed, on the contrary, is of a brown or chocolate color, and is *completely covered* with a mass of short cotton fiber which adheres so firmly as to require scraping with a knife to remove it. We have for some years distributed small parcels of cotton seed to grow as an ornamental plant, as both kinds will generally *bloom* in this latitude and even further north, under favorable circumstances. We put in each paper a few of the Sea-Island seeds to give greater variety of bloom.

How to Germinate Seeds.—S. McC., Nemaha City, N. T. Locust seeds ought to germinate without difficulty if planted early. If they do not, sow with sand, in a shallow box, and set the box in a sunny place, in the ground, top even with the surface. The freezing and thawing will prepare them to germinate in early Spring, when they may be planted. This, it will be seen, is Nature's way of doing the same thing. For the currant and gooseberry seeds, do likewise, except that the boxes should be in a sunless place—like the north side of a fence. If exposed to the sun they may germinate in Winter, and so lose their vitality before Spring. Sometimes we have induced germination in inert seeds by swelling them in very dilute, clear bleaching powder water, about 24 hours. Weak "Chloride of Soda" solution would do as well.

Seed not Injured by Freezing.—G. E. Wheeler, Fond du Lac, Minn. When well dried seeds are not injured by freezing in a dry room.

Basket Willow—Time for Cutting, etc.—S. C. Cut while the bark will yet peel easily, but not till the year's growth is about made, as the better the wood is ripened the better the quality of the osiers. The best time, in this latitude, is usually in September, or possibly a little earlier. New-York is the best market. Of the price at this time, it is difficult to speak, because there have been few sales of the article since the war commenced. At retail, in small quantities, four cents per pound may be considered the current price. Until the war is over, farmers may do better with other crops. Dealers say that much depends upon the quality, and that machine peeled osiers are worth little or nothing.

Grape Roots growing into Mortar.—Hiram Tarbox, of Windham Co., Conn., communicates to the *American Agriculturist* the following interesting fact from his own experience. In a cold grapery, in which three years ago, a pier for a hot-water pipe was laid in clean white mortar of sand and common lime, and at the surface a flat stone was put on, a black Hamburg grape vine was set about two feet distant. The roots extended to and actually grew into the mortar, filling it literally full of fibers. The mortar was of course kept a little damp below the surface. This would indicate that grape roots are fond of, or stimulated to active growth by lime.

The Prettiest Climbing Plants.—"Clara." The question involves too large a reply for our Basket. In a month or two more, we will say something at length on the subject. Meanwhile, a word or two. The Maurandias, pink, white and blue, are favorites with us. The Madeira vine is a very pretty thing in its foliage, the flowers come quite late, and are small, but very fragrant. Cobæa scandens is a wonderfully rapid grower. The Nasturtiums are desirable for the latter part of summer—for fruit (pickles), as well as beautiful for bloom. Phaseolus multiflorus should not be discarded. Of course the various colored Morning Glory is familiar to you.

"Western Plantation Syrup."—This name is adopted as the regular brand for the Sorghum Syrup, after being refined by the "Chicago Sugar Refining Company." This Company offers to receive at any of the railroad stations in Chicago, the crude syrup, as boiled down in the country; to refine it, and to return to the depot 75 gallons of refined syrup for each 100 gallons received. This includes the charges for cartage, cooper work, and the barrels, etc.

Refining Sorghum Syrup.—L. Martin, Sangamon Co., Ill. Your queries are mainly answered on page 42. The process of refining the Sorghum Syrup is a principle somewhat like that practiced at the South for the common cane. The crude syrup is boiled with a small quantity of lime-water, to neutralize any acid formed. The juice is then passed through filters or strainers of bone-black (bones charred by burning so as to fall to pieces). It is then boiled to the desired thickness.

Sorghum Syrup.—Wm. Turke, New-Bremen, has made 1,200 gallons of Sorghum syrup. He ground the cane and evaporated the juice for his neighbors at 25c. per gallon. His syrup sells in New Bremen at 75c. per gallon. The seed is not near as good as formerly, only one half giving good canes. He asserts the need of a new importation of seed.

Sorghum in Michigan.—Almon Maltby writes to the Michigan Farmer, that he manufactured 320 gallons of good syrup from two acres of ground. This from Livingston Co., in latitude 42½°, is a favorable indication of what may yet be expected from the "Chinese Sugar Cane" at the North.

Couch, or Quack Grass.—"C." Groton, N. H. The grass you send is the one named above. It is a detestable weed, but makes excellent hay.

"Skirving's Improved Swedish Turnip."—Some seed sent to us from the Patent Office was sown June 24, on good soil, by the side of other varieties. But after standing in the ground until Nov. 13, it had not a bulb the size of a finger, while the other kinds produced well. As this variety stands high in England, we think the fault must have been in the Department at Washington. We had hoped that after the dismissal of "D. J. B.," no more mulleins would grow from "improved tobacco seed." Perhaps some old purchases of seed may have been left behind. Whoever has charge there should gather up and burn the contents of the old seed drawers, and not trouble the country with them—and himself take warning from the past.

Kohl Rabi.—The wife of a subscriber is informed that this vegetable may be cooked like a turnip or cabbage, and eaten in the same way. Cut in half inch slices to boil and change the water in boiling once or twice. Serve mashed with butter or cream, or not mashed but with drawn butter or cream poured over it. For Winter use they should be treated like a cabbage. Always use them before the eyes in the axils at the base of the leaf stalks start to grow.

Wire Worms.—W. F., of Warsaw, N. Y., has land materially injured by wire worms; by a *course of cultivation*, he has, as he thinks, rid his land of the pest. After giving an account of three experiments to the *American Agriculturist*, he writes: "My opinion is that three crops of buckwheat, potatoes, beans, or peas, will entirely starve out the wire worm. I have found, sometimes, that Fall plowing was best—not always. If land is to be sowed early, then plow in the Fall: if late, it will make little difference, so far as worms are concerned."

Rose Bugs on Grapes.—B. H. S., South Yonkers, N. Y. Your trouble with rose bugs on grape vines is nothing new. This little beetle genus, *Melolontha*, appears annually, sometimes in countless numbers, attacking roses first, but extending their ravages to cherries, plums, grapes, and other plants. The laying and hatching of their eggs, and transformations, are an under-ground work: done out of sight and reach of man. They can be attacked only when in their perfect state, and at their mischief. The females, which constitute about half the number. deposit some thirty eggs each. Like other insects, they have their natural enemies; so every person who crushes a hundred may consider that he is working with the other Heaven-appointed instrumentalities to hasten their disappearance. Poultry destroy a good many, but when abundant these soon become satiated.

Lime for Lice on Cabbages.—Wm. W. Bailey, a lad, writing to the *Agriculturist* from Genesee Co., N. Y., says he was whitewashing a fence by the side of some cabbages badly affected by plant lice, (aphis,) and to try the effect of lime upon the insects. he sprinkled whitewash upon the leaves and stalks, which entirely destroyed the lice.

Security from Bee Moths.—"M," Tipton Co., Ind., thus writes to the *American Agriculturist*: "The bee-hives of all my neighbors, and my own also, suffered considerably from worms. I got rid of them by following the advice of a friend, viz.: Don't put the hives of young swarms on boards, but on bricks, closely laid together, fill the space between the bricks with wood ashes, brushing off all that may lie on top. The moth does not lay her eggs on stones, as the sun does not hatch them out there, but always on wood. My hives have been free from these worms ever since."

Swans at the Central Park.—It will be recollected that the free city of Hamburg presented 12 pure white swans to this City, two years ago, for the beautiful sheet of water in our Central Park. Unfortunately, several of them died soon after they arrived here, but more were subsequently sent. They appear very much at home, sailing gracefully about in the water, and are one of the chief attractions to the thousand visitors daily enjoying the fine scenery of the Park. The swans commenced breeding, for the first time last season, four nests having been made in nooks near the water. Two were deserted after a severe thunder-storm, but from the other two broods of cygnets were hatched. The young might be seen swimming by the side of the old ones, or raising their long necks from the grass which concealed their nests.

Poultry—Weight of Dorkings.—W. J. of Westchester Co., N. Y., referring to the 7 to 8 lbs. weight of "crammed poultry," (January *Agriculturist*, page 9,) says he was led to weigh his grey Dorking pullets of 1861, and found them to run 7¼ lbs. each. The young cocks of same breed weighed 8 and 8½ lbs. Of the older broods, the hens weighed 8 to 9 lbs, and the cocks 10 lbs. each. They were in ordinary condition. He esteems this breed the best for general use, for, besides their heavy weight, they are good layers also.

Chickens.—S. K., Dayton, Ohio. Chickens do better to have a range, but if the crops are likely to suffer by them, they will do very well in the hennery, if allowed but a limited run—enough to secure plenty of fresh air. They should at least be let out awhile morning and evening, and have green food of some kind—grass in summer, and cabbage sprouts, etc., in Winter.

Frozen Eggs.—Sophia J. Damon, of Plymouth Co., Mass., says frozen eggs should be kept in that state until wanted for use, then put in a dish of *cold* water, and set on the fire to thaw gradually. When the water will just bear the finger, they may be broken, and will be found as fresh as when first laid.

Nest Eggs in Winter.—"J. B." If the glass or porcelain eggs can not be had, make imitations of wood and paint white, or make them of chalk. By breaking a small hole in each end of an ordinary egg, the contents may be blown out with the mouth, and the shell used for a nest egg. They will be perfect if filled with plaster, or rosin, or any substance that will set hard, and will not melt by the heat of the hen.

John Sanderson's Large Ox.—Z. D. Bardwell, of Franklin Co., Mass., sends the measurement of a large ox, owned by John Sanderson, in that County, and asks if any of the readers of the *American Agriculturist* can report a larger animal,—"Age of ox, 8 years; girth back of shoulders, 10⅔ feet; largest girth forward of hips, 11½ feet; hight, 6¼ feet; length from between the roots of the horns to the root of the tail, 9⅔ feet; breadth across the hips, 3½ feet; distance from point to point of shoulder, 3½ feet; greatest distance through shoulders, further back, 4¼ feet; length of span, 8 feet; inside distance between the fore feet, as he stands eating naturally, 26 inches; live weight, **3,500** pounds, in October, 1860, since which time he has not been weighed. [Are there no scales large enough in those parts?—Ed.] He has been fed 12 quarts of meal per day—a mixture of corn and oats—and eats as well now as ever. He has the range of the yard, and lies under the barn opening to the East."

A Great Hog.—We have to-day (Jan. 17,) seen a pure Suffolk hog, at 90 Cedar-street, worth looking at. He pretty well fills a one-horse wagon box, and weighs dressed **1,053 lbs.,** or more than half a tun. Live weight on the 14th inst. **1,393** lbs. Age 19 months. Fed and slaughtered by W. H. Libby, on his farm in Madison, N. J. Was imported at 3 months old, from Suffolk, England, by Frank Lathrop, for breeding but became too large and was castrated at 9 months old. Fed on corn meal, milk, etc.

Kind Treatment of Animals Profitable.—The horse serves us with a superior ability and a better *will*, if treated kindly. On the same condition, the sheep gives us a better fleece; the ox, more efficient labor; and the swine, a better carcase. The cow, that is dealt gently with and made contented with her lot, gives us, not only more milk, but of a richer quality, than if ill treated, fretted and made miserable. All animals make a better return, if cared for considerately. "The merciful man is merciful to his beast." He would be so if there was no reward. We owe it to the animals, which are put into our power; we owe it to ourselves: and we owe it to God, who has given us power over them, to make the brief space we intend for them, free from all unnecessary suffering.

Remedy for Kicking Cows.—D. Parker, Jr., of Green Co., Pa., writes: When a boy, I saw an article in a paper stating that tying a cows head a little higher than she ordinarily holds it, would prevent kicking because a cow lowers her head and rounds up her back, when she kicks. My father tried it and found it to answer, except in the worst cases. The remedy has been used in the family ever since.

Mad Itch in Sheep.—G. U. S., Luzerne Co., Pa., writes that "a new disease has lately appeared among the sheep of his neighborhood, called the 'Mad Itch,'" and wishes information. We have never known this name applied to a form of the "scab," to which it might, with all propriety, be given, but presume that this is the ailment—a subcutaneous disease, causing intolerable itching, but not affecting perceptibly the surface of the skin. Youatt says it is not contagious, and recommends housing, shaving, washing with soap suds, and then, every other day, washing with lime water and a decoction of tobacco. We have never met with the disease but should we ever have to treat it, would surely administer flour of sulphur pretty freely in milk, and perhaps turpentine, or tar in small doses, so as to bring the disease out upon the surface, and then treat it like common scab. Diseased animals should be most completely separated from the rest of the flock.

Too Much Opium for Sheep.—In the prize article last month, which was generally correct, a bad error occurred on page 13, which we did not notice until too late to correct it. The writer prescribes a scruple (20 grains) of opium for a sheep. We suspect a sheep weighing 150 lbs. would require no more opium than a man of the same weight. *One* grain of opium, or 20 grains *tincture* of opium (laudanum,) would be nearer the mark.

Why Not Eat the Heart?—On one of the closing pages of this paper, will be found two articles which have cost us a great amount of labor, and which will be well worth studying and saving for reference, viz.: "*New-York Live Stock Trade, for* 1861," and "*Items in a Meat Bill.*" There are several items of a kind never before published together, such as those giving the average weights, shrinkage, etc., of animals, and especially those referring to beeves' offal. But we commenced this to speak of one item there noticed, viz.: that Beeves' Hearts average 6 lbs., and yet sell for an average of only 10 cents each, or 1⅔ cents per lb. We visited a large number of butchers, in order to get at the correct figures in the article, and they nearly all said it was difficult to find purchasers for beeves' hearts at above 10 or 12 cents each. Said one: "If a poor woman comes to my stall to spend her last 20 cents for meat, she will take 1¾ lbs. of steak, and refuse two beeves' hearts, weighing 12 lbs., for the same money." We can hardly account for this, when, pound for pound, the heart is as nutricious as any other part of the animal. *Query.*—What is the best method of cooking and serving a beef heart?

An Aged Cat.—We do not remember to have seen any statement of the age of cats. It seems to be the general impression that, at 6 or 8 years old, pussy is an "old cat," if not *the* old cat. According to the N. H. Jour. of Ag., there is in the family of J. G. Wilson, of Lee, a cat 25 years and 7 months old, as categorically demonstrated by the family register. This must be *the* very old cat. If anybody has an older one let it be recorded in the *American Agriculturist*. Can any one tell us the average age of cats?—that is, of those allowed to live out there natural lives.——It is commonly reported that some cats have "nine lives." What is the length of each life?

Tan Bark for Manure.—We do not think very highly of it, in its crude state. A farmer in our own neighborhood, is now (Nov. 13th) hauling it from the tannery, and spreading it over his meadows, confident that it will benefit them. Good luck to him! For our

own part, if we were to use it, we should employ it first in a dry state, as an absorbent of urine in the stable, then, let it lie in the manure heap a full year, to decompose. A method employed by some, is to spread the tan in an open place, eighteen inches or two feet thick, then shovel on a layer of lime two or three inches thick, then from four to six inches of tan, and so on until all the tan is used up. Wait nearly a year, then shovel the heap well together, and let it lie several months more.

Substitute for Stable Manure.

—"A Novice" inquires of the *Agriculturist*, "What manure would you recommend, in the absence of barn-yard or stable manure, for a small place of two or three acres to be used for vegetable and fruit culture. The soil is good old pasture ground and very rough." ... Go to work at once to make compost, buy (for of course you have money) such articles as damaged glue, leather scraps, refuse bristles and clippings from the brush makers, blood, etc., from slaughter houses, horn shavings, soap boilers waste, fish offal, and we may add, animals of all sorts, particularly old horses. All these things, and others too, may at times be bought much cheaper than any other fertilizers regularly in market, and a good man who takes an interest in it will compost them with earth, turf, muck, soils, or some such material, so that they will be inoffensive and make a very rich manure. Wood ashes, lime, soap boiler's waste, and other alkalies should not be mixed with animal substances, except to force a fermentation in cold weather. In working the soil add bone dust freely and directly, especially where fruit trees are to be set.

Lime.

—"X." asks: After lime is slacked, how long will it remain in a caustic state if kept from the rain as in an open shed?—*Ans.*—Say, six or eight weeks.—It very readily attracts carbonic acid and becomes inert.—Ed.... If it should get hard as for instance, when the water evaporates from a whitewash barrel and it leaves the lime hard and lumpy, can it be easily reduced to powder?—Not easily till it is so dry as to be readily powdered.—Ed..... Is it right or wrong to mix lime with the muck which is to be used in the stables, or cow yard?—Right, three months beforehand.—Ed.

Manure in the Cellar.

—G. W. S., Gilmanton, N. H. Were fresh manure, that is dung and litter mixed and unfermented, to be applied *and plowed under*, there would be no loss of any thing. When manure lies in a cellar or well made dung heaps, or compost heaps, it ferments and *should* lose only carbonic acid and water, a small quantity of ammonia is doubtless lost, but it is very small, if the manure heap is kept compact and moist.

Top Dress Meadows.

—As soon as the grass is cut if you have, and you should have, fine rich compost. Manure from the dung heaps (more or less rotten) may be applied late in autumn or early winter, before the ground freezes.

"How to get and Use Bones."

—H., says he is at a loss. "They cost too much." The boys will collect them for a few cents a bushel about the village. Many may be saved in the family, and with a little care you will be able to collect plenty at a price not to exceed ¾ cent a pound.

To Dissolve fresh Bones.

—There is no Patent on the method and it is worth 25 years subscription to the *Agriculturist*.—*Pound them up fine and feed them to hens.* This is the best time of year, though it is good at all seasons.

Hulled Corn and Hominy.

—J. C. Brattleboro', Vt. We know of no machine for hulling corn by hand. There was a Hand Corn Huller in the market six or eight years ago, but nothing has been heard of it of late, and it has probably gone out of use. Perhaps here is a small field for an inventor.

Bob Sleds—Double Sleds.

—Bob sleds are well known in new, woody, snowy regions, as sleds with very short runners, designed for long timber, one end to draw on the snow. When an extra pair of runners are attached, for sustaining the hind end of the timber, or of a rack, if one be used, they are called double sleds. A subscriber in Maryland (W. Edmondson, of Ellicott's Mills,) sends to the *Agriculturist* a strong recommendation of them, claiming (1,) that the double sled runs more lightly than the single long runners; (2,) that it is more convenient for turning; (3,) that it is stronger, and carries its load over rough ground with more ease and safety. He thinks it would be useful to farmers, if we were to describe the double sled, with directions for making. At present, we can only say: the runners are to be short—say 3½ or 4 feet, and very strong; the tongue, like that of any other sled, lighter, if for horses, and heavier, if for oxen; and the connecting rod between the two pairs of runners, to be jointed near or at the beam of the forward runners, and to be so attached to the beam of the hind runners, as to admit of lengthening or shortening the distance between the two beams at pleasure.

Cleaning Spelt.

—"Meyer," Tipton Co., O. A full description of spelt or "Dinkel," is given in vol. 19, p. 104. As there stated, the chaff adheres so closely to the grain that a hulling or chaffing mill, similar to a rice mill, is required to prepare it for grinding into fine flour. These spelt mills are common in Germany, and will soon become so here, if it be found that the grain can be profitably grown in this country. This is the first thing to be established, and to have this tested is our object in distributing the seed. In Germany it yields well on soil that will not produce wheat. There will be no loss in the trial, for the grain is valuable to feed, and is thus used in some parts of Europe, where it is not needed for human food. [Many thanks for "Meyer's" kind words, and those of his good wife. Such opinions are worth working for.]

Steam Plowing.

—Mr. Robert Walkington, North Ormsby, Eng., having furnished himself with Roby & Co.'s 10 horse engine, and Smith's 5 tined, patent cultivator, for running 9½ inches depth, gives the following as the result of his experience thus far: cost of plowing 238 acres by steam, $140,48; estimated cost of doing the same equally well with horses, $389,62; difference $249,14. It is rather hard to believe that, if the interest on the cost of machinery, its depreciation by use, etc., were fully estimated, the difference would appear as great as this.

Novel Method of Filling an Ice-House.

—A gentleman residing at New-Hartford, Conn., has a pipe, leading from a spring above, pass through his ice-house. This is pierced by numerous small holes, and when the weather is very cold the house is thrown open and water turned on. The fine spray and jets freeze as they fall, and in a few days, or weeks at furthest, the house is filled with one solid "lump of ice," with no labor of cutting and hauling. So says the Winstead Herald.

The Royal Cheese.

—An inquiry in the *Gardener's Chronicle*, in regard to a monster cheese presented to the Queen by the Somerset folks, elicited these facts: "The inhabitants of West Pennard, a village near Glastonbury, Somerset, in order to prove their loyalty, resolved that a cheese should be made from the milk of all the cows in the parish, and when ripe, should be presented. An immense vat was prepared, embellished with the royal arms, etc., and on the anniversary of the Queen's coronation, 50 of the wives and daughters assembled, with *one meal's milk* from 726 cows. This amounted to upwards of 20 hogheads, and occupied the contributors from morning until night to turn it into curd. When finished, the cheese was 9 feet in circumference, 3 feet 1 inch in diameter, and 1 foot 10 inches thick. It was presented to the Queen Feb. 5, 1841." It makes little difference whether it was presented in 1841 or 1851. Carelessly written, they look much alike. The date does not affect the fact that it is one of the largest cheeses on record.

Knitting Machines—Ice.

—S. D. J., Ripley, O., inquires, whose is the best knitting machine? and whether ice-houses are not better, built underground? If any one knows of a good *family* knitting machine, he should make it public. Ice-houses built above ground are more convenient, and, if built rightly, are good enough, for they will keep ice the whole year, and will make an adjoining room cool for meats, milk, butter, etc. But they must necessarily be somewhat expensive, or make but an indifferent appearance. Where the most rigid economy is desired it may be better to build wholly or partly underground.

Removing Smoke Stains from Marble.

—"S." of Essex Co., N. J., says he removes smoke stains from marble mantels, by applying a little chloride of lime (obtained at any druggist's) wetting the chloride with water to form a paste. This will doubtless take out the stains, if they are made by smoke, but we are not certain that it will leave the polished surface of the marble uninjured.

Quick Work.

—Owing to the breaking of a Paper Mill shaft, the contractors were likely to get a little behind in supplying the paper for the December *Agriculturist*. Night came and the presses must needs stop unless a supply could be obtained by the next noon. One of the firm (of Seymour & Co.) left the City and reached the mill at Morristown N. J., at 7 P. M., and ordered paper to be made. At 10 o'clock the next morning, 16,000 sheets of paper had been manufactured, calendared, cut and delivered at our press rooms in this City, giving a supply for the day. A portion of this was printed, folded, stitched, and mailed, and was on the way to subscribers at 2 P. M., or within 19 hours of the time the order reached the Mill at Morristown, 30 miles from the City.

Profanity

—A few days ago, says a correspondent, a boy was using very profane language. He was talked with kindly, and shown how wrong he was. He seemed quite sorry, and, looking up with a tear in his eye, said, "Well, who was the first person I ever heard say bad words?—it was my *father*."—Did his father think what a lesson his words taught?—Ed.

Usefulness of Canals—N. Y. City and the Country.

—During 1851 the freight brought to New-York City through the Erie Canal and its connections, (the Champlain, Oswego, and Genesee Canals,) amounted to **1,531,529 tuns**, or **3,063,058,000 pounds**, valued at **$50,905,253**. Nearly all of this was agricultural products. The freight *from* New-York by the same routes was 93,778 tuns, valued at $20,790,404. This would show a very large balance of trade against the City in favor of the Country. But this balance is in part reduced by the fact that the freights *to* the City were mainly of a heavy character, grain, etc., and these passed over the canals, while merchandise from the City was more costly, and was more generally sent by railroad. Not a little of the balance, however, went to cancel debts of the country to the City, contracted in former years.

New Use for Diamonds.

—A circular from Montreal, L. C., describes an invention of Mr. J. Dickinson, by which a diamond is used for dressing the surface of millstones, instead of the steel pick now employed for that purpose. It is said that the lines cut by the diamond upon a new stone, are clear and distinct, with sharp cutting edges, and that they will remain in good order longer, and perform better work, than where the stone is dressed in the ordinary way. But (1,) where are we to get all the diamonds needed, and at what price, and (2,) are real diamonds large enough to "pick" mill stones?

To be an Editor.

—"Franklin," of Pa., wishes to become an agricultural editor, and to be advised about schools, etc.....Don't think of such a thing. Go to Dr. Pugh, at the Penn. Farm School, if you will, but do not try to be an editor unless you see you are unmistakably qualified, and then do it as you would enlist for the war or go a missionary to Madagascar—from a sense of duty.

An Odd Abbreviation.

—The word "*Ibid*" which may often be noticed appended to articles taken from the *American Agriculturist* and printed in other journals, is an abbreviation of the name of this paper. Our readers will bear this in mind whenever they see *good* articles thus credited to "*Ibid.*"

Good Crops.

—Geo. A. Elston, of Bradford Co., Pa., writes that his 12 acres of wheat threshed out 300 bushels (25 bushels per acre) of plump grain weighing 62 lbs. per measured bushel. His oats averaged 55 bushels per acre. These are very good crops for that section of the country, though 25 bushels of wheat per acre would not be thought much in many other localities. We like to hear of these good crops, but can not find space for publishing many such reports, because we prefer to occupy the pages of the *Agriculturist* in telling *how* to produce big crops. To tell Mr. A. that Mr. M. got 60 bushels per acre, may be pleasant news, or it may not be. If he does not know how to get 20 bushels, it may be discouraging. But tell him *how* Mr. M. gets 40 bushels and you will do him good, both in feelings and in purse.

Coal Tar.

—A correspondent writes concerning this article: "On corn it is an effectual remedy against fowls and birds. Late in the Summer I applied a coating of coal tar to the roots of young peach trees, and on a recent examination, all appeared healthy and free from worms. Will some reader of the *Agriculturist* who has tried its use for long periods give the result?" [We have heard of injury resulting from painting the stems of trees with coal tar.—Ed.]

Remedy for Poison by Ivy in Meadows.

—Wash, or, if convenient, soak the part affected in strong bark, or tan liquor, which may be prepared by boiling oak bark. So says a correspondent of the *Agriculturist*.

Driving Rats with Powder.

—James Goodwin, of Columbia Co., Wis., says, "Tie up a teaspoonful of powder in a cotton rag, and tie this to the end of a piece of blasting fuse, and push it in the rat holes as far as possible. Ignite the fuse, and before the fire reaches the powder the rats will be off on the 'double quick.'"

Lime upon Lime Soils.—R. R. Bryan, of Blair Co., Pa., writes to the *Agriculturist*: "I desire information on the subject of applying lime to limestone soil. I have plowed and subsoiled some sixteen acres of heavy sod for corn, the subsoil plow loosened the yellow earth about five inches below the bottom of the 8-inch furrow. It is called "limestone clay," and I am hesitating about burning lime, as it may be there is lime enough in soil." . . . It is an important fact that the action of lime, (fresh slacked) is often most favorable upon limestone soils. This not by virtue of its being valuable as plant food, but because it produces some favorable chemical and mechanical effects upon the soil. By all means make the trial.

Muck.—E. Gould, Wash. Co., N. Y., wants to know how to prepare muck for use, has large supply, some say burn it and use the ashes, others say slack lime in it to sweeten . . . Dig in the Winter or before; let it lie and freeze and dry; when it can be handled, mix it with manure in the barn cellar, yard, or compost heaps; or make a heap using 3 to 5 bushels of fresh slaked lime to a cord of muck, spreading the muck in six inch layers, and throwing the lime over it. Work the heap over in about ten days, and use it on the land in three weeks, or, as an absorbent with cattle manure after three months.

Carrot Tops for Dycing.—"In the vicinity of Hartford," writes a subscriber whose daughter is in East Hartford on a visit, "carrot tops, mown off, sell for $30 a ton, to be used in dyeing blue cloth." (We don't understand how the *blue* color is obtained.)

Humbugs to be Avoided.—"Free Lottery Tickets for Agents," sent to Canada, (and every where else,) by B. B. Holt, and Th. Owens & Co., hailing, at present, from Progress, N. J. *Also*, "Grand Social Banquets," "Mechanics' Union Clubs," etc., at Salem and other towns in New-Hampshire, including George Hamilton, James R. Lawrence, and all others who write letters offering to procure $100 prizes by lying, for the small sum of 25. If they tell one lie, as they offer to do for $5, they will tell another one and keep the $100—*if* drawn. *Also*, "Doctors" in Northern New-York, and elsewhere, offering $30 for distributing circulars, *if* you send 25 cents for entering your name on their "Agents' Books." *Also*, those hailing from Boston and elsewhere who offer you $20 to $30 a week if you send $1 for a pamphlet of instruction. (Why did not H. H. M. & Co, stay in England and Ireland, if they found "over 10,000" fools there?) *Also*, any one in New-York who offers $20 to $100 a week for selling sewing machines, if you will first send them $5 for a "sample." *Also*, "Rev." Edward A. Wilson, of Williamsburgh (whom we can never catch "at home"). *Also*, his *aliases* in New-York and Brooklyn, who offer cures of consumption free. *Also*, sellers of Japanese Wheat. More hereafter.

Corn Meal—To Make it Keep Sweet.—In a letter just at hand from Mrs. O'Brien, who received the first premium for Corn Bread, she says: "If you take corn meal when purchased at the market or grocery store, and put it in a pan and leave it warm in a warm stove-oven over night, it will keep better, will acquire a sweetish taste, and will rise and bake better. The little trouble to do this will be amply repaid. . . . I do not like scalding meal before using, as it tends to make it clammy, and can do little if any good; drying the meal is safer and better."

Cheap "Wringers" worse than Useless.—Just now there is no little excitement about wringing machines, and since a good article is found to be useful, the country is being flooded with all sorts of cheap affairs, from $1 upward. We must caution the readers of the *Agriculturist* at least, that as yet there is no wringer before the public worth buying which has not two cylinders, *thickly* coated with India Rubber, (at least half an inch thick all round;) and that these cylinders *must* be made to turn together by connecting cogwheels. Without the cog-wheels the rollers are liable to slip and tear the cloth, no matter how strongly it may be asserted to the contrary. Without the thick rubber, the instrument will not do its work well. No *good* wringer can be sold at retail for $5, at the present price of India rubber.

Come Round Right at Last—The Tribune on Premiums.—Years ago, the Publisher of the *Agriculturist* acted upon the idea that it would be just, and more pleasing all round, to offer pay, in the form of good articles, to those who took the no small trouble of getting up and forwarding large lists of names, instead of making begging appeals to them, to "work for the good of the cause." He also thought to do a good work for the country by sending out new or desirable seeds for propagation and a wider diffusion. But what a hue and cry was made! "Humbug" was the quite common slur of the press. We remember the Tribune gently hinted that the *Agriculturist* was not intrinsically worth the price asked for it, but needed a little of something else "thrown in" to make it worth a dollar a year.—But what a change! Now, nearly all enterprising journals, religious, scientific, agricultural, news, etc., are offering premiums (pay) to canvassers. Many of them have "stolen our thunder," and doubled it; and, tell it not in Gotham, even the Tribune has come round right at last, for it now pays agents for services rendered, by supplying them with writing apparatus (pens.) Very good, Mr. Tribune. Now, having had more experience than you, let us advise you to add some white paper and a bottle of ink, and then you will do some good seeds as we do, to complete your agricultural department, and you will make your paper, *with the extras*, worth its price . . . . (Are we "square" now, Mr. Tribune?)

Hogs—Cost of Bringing to N. Y.—Jan. 9, Messrs. Zeublin & Hardy, of Pendleton, Madison Co., Ind., (28 miles Northeast of Indianapolis, on the Belfontaine Railroad,) shipped 465 live hogs on that road. The average weight was 261 lbs., and they occupied 8 single-decked cars. The lighter hogs went 65 to 68, the heavier ones 51 to 53 to the car. The cars were forwarded to Buffalo, taking the Columbus and Cleveland road at Galion. The freight from Pendleton, Ind., to Buffalo, was $72 a car, which included return passes for three men accompanying the hogs. Average freight per hog, $1.24 to Buffalo. Time to Buffalo, 60 hours. Two hogs died and were sold at Buffalo to 1¾ cents per lb. Cost of feed and hotel bills, during 2 days detention at Buffalo, $25.—From Buffalo to New-York, by Central and Hudson River Railroads, five double decked cars were required. Time through, about 40 hours. Freight through, 47¾ cents per 100 lbs. They were called 108,616 lbs., and the freight $515.92, or $1.11 per hog. Free passes were given to the three men while with the hogs, but no free passes to return to Buffalo. Whole cost from home for 465 hogs, $1,116.92, or $2.40 per hog—a trifle less than one cent per pound, on home weight. To this is to be added in New-York, 3 cents each for yardage, 1 cent each for weighing, cost of the feed, and 1¾ per cent commission for selling. The shrinkage will be about 90 lbs. per hog, or 8 lbs. to the cwt. These were larger than the average run of hogs, making the freight a little higher for each.

Farmers' Tricks of Trade.—The following from a correspondent needs no comment: "Of two Long Island farmers, one warmly contended that *custom* sanctioned putting the largest and finest potatoes, apples, pears, peaches, etc., on top of the basket or barrel, for if this is not done, they bring lower prices. The other, who was more conscientious, said he could not do it, notwithstanding custom sanctioned it, and he was aware that he got less for his fruit and vegetables than his neighbor did. As a buyer for family use, I listened attentively, and regretted to find that the majority of buyers, or market men, at least, are thus paid a premium for what I should term deception, if not dishonesty. For a long time I have observed this tendency to make the finest show upon the outside; and when I wish to buy a basket of apples or peaches, I have to ask the dealer to pour them out, to see how the bottom compares with the top. What says the *Agriculturist* to so glaring an evil? Shall we not rather encourage uprightness in the dealings, than countenance deception in any way? I know of parties who have bought what they supposed to be fine baskets of fruit, judging from the outside appearance, and finding them so very inferior generally, they have resolved never to deal with such sellers again. As it now is, a person is certainly liable to be deceived, unless he overhauls every package of fruit or vegetables coming to market. As far as one purchaser is concerned, I am resolved to purchase of such persons as the conscientious dealer referred to, when I can thus encourage honesty rather than duplicity."

Cotton Speculation in England.—It is stated in English papers that almost every body in that country is infected with the mania for speculating in Cotton. Clergymen, doctors, lawyers, and even ladies are investing, in hopes of speedy fortunes. The effect will be *bale*-ful, when the bubble bursts.

Vermont Farm Scene Wanted.—Honestus Stearns, Windsor Co., Vt.—Good. We endorse your criticisms on the November *Agriculturist*. Can't you give us a real genuine Vermont Scene?—a picture of one we mean.

The Parlor Gardener.—A very neat concise little book, on the House Culture of Ornamental Plants, full of suggestions, in the main reliable, and expressed in a playful style. Translated from the French and adapted to American use, by Cornelia J. Randolph, of Virginia. Published by J. E. Tilton & Co. There are several fine cuts of table ornaments, in the plant line, and the book is well worth the price (65 cents). Sent post-paid.

To Onion Growers.—We have a neat pamphlet of 32 pages, containing the condensed but plain directions given by *Seventeen practical Onion Growers*, residing in different parts of the country: and embracing full directions for every item of labor, from selecting seed and preparing ground, to harvesting and marketing crop. Nowhere else can so full, complete, and useful information on this subject be found. Sent post-paid on receipt of 21 cents (or seven 3-cent stamps). Address the Publisher of *American Agriculturist*.

Of Stationery, Blank Books, etc., Francis & Loutrell, No. 45 Maiden-lane, manufacture a large assortment. We acknowledge the receipt of a very fine Pocket Memorandum and Daily Diary for 1862, which we are turning to practical *account*, daily.

Books on Trees and Shrubs.—W. H. Baker, Racine Co., Wis.—Meehan's Hand Book of Ornamental Trees (75c.) is the best American work, for a cheap popular book giving descriptions and methods of propagating, condensed in a small compass.

Iowa College Farm.—Nearly the whole of the $10,000 appropriated by the Legislature of Iowa for agricultural purposes, was expended in the purchase of a farm, in the erection of farm buildings, and in setting out trees and otherwise commencing farm operations. An Iowa correspondent of the *Agriculturist* says, that little or nothing is now doing, but that the college farm interests are secured against loss, and will probably so remain till peace returns.—A wise arrangement.

American Pomological Society.—Ninth Biennial Meeting, at Boston, Sept. 17th, 1862. We learn by a note from the President, Hon. Marshall P. Wilder, that the next meeting of this association will open as above. Previous meetings have been held at New-York, Boston, Philadelphia, Cincinnati, and Rochester. This is the only National Society, devoted to horticulture or agriculture, which has deserved and enjoyed a successful career. It has eschewed all financial speculations, and money raising dodges, and thus kept free from a class of harpies who invariably attach them selves to every national enterprise, when there is and money to be made, and if not shaken off bring it to disgrace if not ruin. The friendly meeting of fruit lovers, for a calm discussion of the real merits and demerits of the different varieties of fruits, is productive of good to themselves and to the country at large. We can but hope that before next September, our National troubles will be so far settled that, as in the past, the Pomological Meeting will be a *National* one.—The Massachusetts Horticultural Society has ordered its Annual Exhibition for the same week.

Conn. Grape Growers' Association.—The Annual Meeting was held at Hartford, Jan. 7th. The election was deferred to an adjourned meeting to be called by the Executive Committee. Present officers: *President*, D. S. Cheever, Bridgeport; *Vice Presidents*, S. Middlebrook, Bridgeport, and E. A. Holcomb, Granby; *Secretary*, Mason C. Weld, (now) N. Y. City.; *Treas.* W. H. Risley, Berlin.

The Kentucky Agr. Society.—Held its annual meeting early in Dec., and re-elected Col. L. J. Bradford, of Bracken Co., for President, and chose for *Vice Presidents*—P. Swigert, Franklin Co., 1st District, J. B. O'Bannon, Jefferson Co., 2d Dist.; Jno. G. Holloway, 3d Dist., with 5 directors for each district. The President in his address stated that the Annual Tobacco Fair at Louisville, had added (annually?) $2,000,000, to the value of that staple in that State.

Conn. State Agr. Society.—At the Annual Meeting, at Hartford, Jan. 8th., the following officers were elected for 1862: *President*, E. H. Hyde, of Stafford; *Vice Presidents*, R. Battell, of Norfolk, and D. F. Gulliver, of Norwich Town; *Cor. Sec.* Henry A. Dyer, of Brooklyn, Windham Co.; *Rec. Sec.* T. S. Gold, of West Cornwall; *Treas.* P. A. Brown, Hartford; *Chemist*, Prof. S. W. Johnson, Yale College, New-Haven; *Directors*, (appointed by Society, one for each County).—Chas. M. Pond, Hartford; Randolph Lindsley, New-Haven; James A. Bill, New-London; E. Hough, Fairfield; Levi Cowles, Middlesex; Lemuel Hurlburt, Litchfield; Benj. Sumner, Windham; R. B. Chamberlin, Tolland. *Directors* (appointed by County Societies)—J. A. Hemmenway, Hartford; N. A. Bacon, New-Haven; Henry Bill, New-London; G. W. Seymour, Litchfield; Ezra Dean, Windham; Stephen Hoyt, Fairfield; J. S. Yeomans, Tolland; no one yet nominated from Middlesex.

New-York Breadstuffs Trade, Meat Trade, etc., for 1861.

We hardly need call attention to the condensed, but very complete tables in our Market Review on pages 58 and 59. They have been prepared for the *American Agriculturist*, with much labor and great care, and our readers will be able not only to see at a glance, the trade of the year just past, but also to compare this trade with that of the previous two years. These figures explain the improved condition and feeling of the country, even in the midst of war. The prices of farm produce, in the Western market towns, have not been high, as compared with a few years ago, yet the amount of money sent westward for produce, in the year 1861, was enormous, as compared with previous years. Let us look at table **3** (page 59), showing the receipts at New-York for each of three years, and see what amount has been paid to producers for Breadstuffs, through the direct channels of trade. (The receipts are only those coming through regular channels, and recorded. Large amounts, purchased to arrive, have gone directly to receivers, without any record being made; and much has come in by transient routes.) The prices used in the following estimates are the average of all sales made throughout the year.

RECEIPTS AT NEW-YORK FOR **1861.**

Kind.	*Amount.*	*Average Price.*	*Value.*
Wheat Flour	4,968,971 bbls.	at $5.40.....	$26,832,443
Wheat.....	28,429,125 bush.	at 1.35.....	38,379,318
Corn	20,726,166 bush.,	at 60.....	12,435,699
Corn Meal..	98,519 bbls.,	at 3.06.....	301,468
Rye	775,665 bush.,	at 72.....	561,478
Barley.....	1,854,394 bush.,	at 68.....	1,260,926
Oats	4,852,009 bush.,	at 36.....	1,746,723
Total for Flour and Grain.....			$81,518,055
To this let us add the amount paid for Live Stock, as given on page 58,)			.....$22,485,816
Total for Breadstuffs and Live Stock...			**$104,003,871**

This is without taking into account the irregular receipts of Grain, Live Stock, etc., nor does it include salt meats, poultry, lard, butter, cheese, eggs, potatoes, fruit, wool, hay, hops, seeds, tobacco, etc., etc., received at this single market, tables of which would fill a large volume.

Range of Prices in 1861.—For future reference, we have prepared the following table of the New-York prices of leading articles, on the 20th of each month during 1861. For the *average* of the whole market at any time, we may take: for *Flour*, the highest quotations of "Extra State"; for *Wheat*, the highest quotations of "All kinds of Red"; for *Corn*, the highest quotations of "Mixed"; for *Oats*, the highest quotations of "Western."—The average prices used above for flour, wheat, and rye, are higher than in the table below, because more of these three articles were sold at the higher than at the lower monthly figures.

NEW-YORK PRICES, ON THE 20TH OF EACH MONTH.

1861.	*Flour.* $ c.	*Rye Flour.* $ c.	*Corn Meal.* $ c.	*Wheat* $ c.	*Corn* c.	*Oats.* c.	*Rye.* c.	*Barley.* c.
Jan..	5 55	3 72	3 35	1 38	71	37	74	72
Feb.	5 50	3 71	3 30	1 35	68	37	67	74
Mar'h	5 45	3 70	3 02	1 35	68	33½	64	72
April.	5 40	3 70	2 97	1 40	68	35	68	67
May..	4 35	3 50	3 00	1 32	53	32	67	61
June.	4 95	4 50	2 97	1 30	45	31	68	57
July..	4 50	3 90	2 91	1 12	50	31	67	57
Aug..	4 50	3 90	2 95	1 30	50	33½	60	—
Sept.	5 45	2 90	3 05	1 30	56	35½	69	70
Oct..	5 80	3 40	3 00	1 26	61	39	74	65
Nov..	6 00	3 75	3 07	1 44	67	47	83	76
Dec	5 85	3 80	3 30	1 43	67	43½	84	73
Avge.	$5 30	$3 46	$3 06	$1 37	60	36	70	68

In looking at the prices given above, the first suggestion perhaps will be, that these are far above those received by producers. But these prices have been paid here, and all the money paid has gone *towards*, and *into* the country—some to laborers on the lines of transportation, and some to dealers, all of whom live in the country or in interior towns, and spend the proceeds of their labor there. The main point we aim at is, to show how much has gone to the country from this single City. Much of the amount paid for Breadstuffs has come to us again from over the ocean, either in return cash, or in cancelled debts owned to foreign countries, and by so much has this country been enriched.

The Tables in the Review are interesting also in the comparison they give with other years. Thus, the receipts of Wheat in 1861 were over twenty-eight million bushels; in 1859 they were less than four millions. Receipts of Corn in 1861 were over twenty millions, in 1859 less than four millions. So of Wheat Flour and of Rye.

The prospects for the future seem to be encouraging. We stated last month Dec. 20, (which by mistake was printed Oct. 20,) that we did not believe there would be war with England. The prediction has, happily, been confirmed. There is no present prospect that the outlet to our farm produce, to the hungry foreign markets, will be interrupted. All the Breadstuffs we can spare will doubtless be wanted before the next European harvest, and the avails will add so much more to the actual wealth of this country.

Sandwich Island Agriculture—Interesting Items.

A subscriber (Joel Bean, a Missionary of the Society of Friends,) at Honolulu, the chief city of Oahu, and the capital of the Sandwich Islands, in a recent letter to the *American Agriculturist*, gives the following interesting items: The only land suitable for cultivation on these Islands is the narrow border, varying in width from one to ten miles, between the mountains and the sea shore. Most of this is at present pasture land, and plentifully stocked with cattle and horses, and some sheep and goats. It is said that on the Island of Oahu, there are as many horses as people. This almost universal grazing of the land, increases its parched appearance during the dry summer months, and in some places the rains have sensibly diminished, since the cultivation of the ground ceased. The stranger is struck with the very small proportion of land under tillage, and wonders how the people are fed. But the native population subsist principaly on *Taro*, of which their little patches are to be seen around every village. This plant yields abundance of food. [The *Taro* is a plant of the genus *arum*, having leaves like the water lily, and large, thick, oblong roots, which are baked and used as food.—ED.] A little corn is raised, together with Irish and sweet potatoes, melons, and small quantities of garden vegetables. On the island Mani, wheat is raised, and there are several large sugar plantations. But wheat is an uncertain crop, on account of worms, and a portion of the cane which requires in some localities two years to mature, is now quite ruined by the drouth. The present neglect of agriculture has grown out of a dependence on the whale shipping, which a few years ago was a very great source of income, but since that business has diminished to a great extent, those in authority and others interested in the prosperity of the Islands are being aroused to the necessity of developing their own resources. Hence, strenuous efforts are now being made to introduce cotton growing on a large scale, and to interest the natives in its culture.—But little of the land is fenced or under cultivation. The principal material for fencing is stone; in some places wire is used; and now and then a lot is enclosed by a hedge of prickly pear. The cultivated fruits are: bananas, papia, figs, grapes, etc. The wild fruits are ohias (native apples), ohelos (a kind of huckleberry), pohas, strawberries, bread-fruit, guavas, and some oranges in the mountains, but none of these fruits are abundant, except bananas, which are of more general production than any of the others.

Farmers be Sociable.

The position and duties of farmers somewhat hinder their sociability. Scattered over the hills and valleys of the country, often miles apart, and engaged in solitary field labor, day after day, and month after month, it is not so easy to keep up much intercourse with general society. Mechanics, merchants, manufacturers, and professional men, naturally concentrate in cities and villages, where they can enjoy a daily exchange of opinion and information, and pleasant courtesies. This stimulates thought, awakens ambition for improvement, and adds much to the general happiness of life. The longer farmers live in a solitary way, the less likely are they to change their habits. It is not surprising that in many cases they become stiff and awkward in their manners, dull in intellect, and ungenial, if not morose in feeling.

But we are not, on this account, going to depreciate the farmer's lot: it is, in many respects, the best under the sun. Yet it can not be denied that evils lie in the direction we have indicated; *and they should be guarded against.* It is not a good thing for anybody to make a slave of himself: to jog around as in a treadmill, year after year, with little or no relief, or rational enjoyment, and the farmer should not follow his work too doggedly. We would not have him drudge so hard that he can not enjoy the society of his family every day. He ought to be the leader and benefactor of his household in their social intercourse. His conversation at the table, and around the evening lamp, should be instructive and elevating to sons and daughters. His genial hospitality should attract neighbors and friends to visit him often and enliven the converse of the fireside. And he, with his family, should systematically keep up acquaintance with other good families, far and near.

The Farmers' Clubs, which are established in many districts, exert a good social influence so far as they go, but they are not enough; the intercourse of families should be superadded, as this contributes very much to the enjoyment and respectability of agricultural life. It lightens the burden of daily toil, relieves its solitariness, awakens thought, and promotes general improvement. Where this is done, farmers' children, both sons and daughters, will be less inclined to long after the excitements and gayeties of town life, and more of them will be content with the calling in which they were born.

Apple Juice for Dyeing.

According to English Journals, the discovery has been made by Manchester dyers and calico printers, that apple juice is just what has long been wanted for making fast colors of some descriptions on printed cottons. Numbers of them have been through the adjacent counties buying up the apple crops which have heretofore been used for cider, at advanced prices, and a scarcity of the latter article is apprehended. Our own enterprising dyers and calico printers have already made the application and it is used as a substitute for argols and cream tartar in various processes. The state in which cider is of most value is hardly yet definitely ascertained—whether as new cider, hard cider, or vinegar.

POULTRY AND PORK.

Engraved for the American Agriculturist.

Our artist has sketched a picture not uncommon among American farm scenes. No farm establishment would be complete without its poultry yard, and its piggery. The frugal housewife well knows the advantage of a basket of eggs for the Store, to be returned in a few yards of muslin or calico, a spool or two of thread, a packet of tea, and sundry other "notions." She has received many six-pences and shillings of "pin-money" from the peripatetic chicken merchant. She fully appreciates the convenience of plenty of fowls in the roost, always ready to be drawn upon for an extra dish, when an unexpected friend arrives. Her poultry are therefore sure to receive their regular rations, whether the vegetable and flower garden be neglected or not. The artist has introduced into the back-ground the never absent trough and feeding porkers. The two objects suggest the inquiry, which *pays* the best, poultry or pork? Much may be said on both sides of the question, but as a rule we should decide in favor of poultry, notwithstanding the argument, considered as unanswerable, viz.: that the pigs will consume and turn to profitable account a large amount of garoage that no other animal will eat. This is an error. Barn-yard fowls will devour almost every species of garbage that the porkers will not turn up their noses at—*salt* kitchen slops excepted. The only serious objection to poultry is, that they do not flourish well when kept together in large numbers. But this objection is without force on most farms where only a hundred fowls, or so, are kept, and around the thousands of smaller homesteads, where a pig is considered necessary as a scavenger. It seems not to be understood that fowls are preferable for the same purpose. We will let a subscriber speak. Here is part of a letter just at hand from J. C. Thompson, of Staten Island:

"Most families in the country, and on the outskirts of cities, think they must keep one or more pigs, to use up the offal of the family—or because it is the 'custom of the country.' Having tried pigs, and become disgusted with the trouble, labor, expense, filth and noise—to say nothing of the inferiority of pork to eggs and poultry—I abandoned the former for the latter; the result has been quite satisfactory, and after several years trial, I feel confident the advantage is decidedly in favor of poultry. Here is my last year's account:—January 1, 1861, stock on hand, 70 fowls, of which fifteen died during the winter, from unknown causes, leaving me 52 laying hens. From these I obtained in January, 409 eggs; in February, 439; in March, 681; in April, 959; in May, 835; in June, 801; in July, 719; in August, 603; in September, 421; in October, 332; in November, 286; and in December, 440. Total, from 52 hens, 6,925 eggs—equivalent, in bulk, to seven barrels, as a barrel packed for market contains just about 1,000 eggs. About 8 eggs from the Leghorn or Black Spanish breeds, weigh a pound. My 6,925 eggs therefore weighed 865 pounds. Allowing the hens to weigh 5 pounds apiece, they each laid, on the average, *three times* their weight in eggs alone. As they hatched full a hundred chicks, the weight of which, when ready for the table, must have been 1½ pounds each, the whole amount of food produced was over a thousand pounds, notwithstanding I killed off part of the old stock in June, July, and August, depending on the Spring-hatched chicks, which began to lay in August, to keep up a supply of eggs and replace those killed off. When we consider the amount of food (of the very best kind) produced in one year, from so small a stock to start on, and then, too, the stock left *whole* at the end of the year—the advantage of poultry over pigs can be seen at a glance.

To produce 1,000 pounds of pork, will require a vast amount of labor, a vast quantity of food, and any quantity of noise—giving fresh food for only a short time, and salt food for the balance of the year—and the stock not left whole to start on again, as in the case of poultry. The product in eggs was more than 6,925, perhaps over 7,000, as I detected a boy that had access to the hen-house for some time, in stealing them. The number named was actually collected. My stock is principally Leghorn; and it now costs $3 per month to feed 75 head. As some may desire to know *how* the hens are managed, I send a brief description." [We will try to find room next month for the details of Mr. T.'s practice; it is well to know first *what* is done, but the *how* is not less important.—Ed.]

Maple Sugar.

The maple sugar season is just upon us. Always important as it is, this year it is more so than ever. The high price of cane-sugar makes it a costly luxury, to be indulged in sparingly. Moreover, it will do us northerners no harm to be thrown a little more upon our own resources. With the maple-trees and the sorghum plant, we shall get along quite comfortably.

The "sugar-bush" should always be securely fenced in; it is a great annoyance to have one's buckets visited by roving cattle during the night. The apparatus used *may* be of the rudest kind—the "buckets" mere blocks of wood dug out with an ax, the sap boiled down in kettles hung on a cross-bar in the open woods—but then, the molasses and sugar will be rude, too. We can easily do better than that.

First—the conveniences for boiling down. Build an "arch"* of brick and mortar, in size corresponding to the extent of the bush. On this, large pans are to be set for evaporating. Two or three cross-bars of iron are to be laid across the opening, to prevent the pans from sagging down. The pans should stand exactly level. Any tinner can make the pans, using Russia iron, two sheets riveted together with sides 5 or 6 inches deep turned over ¾ wire, and provided with handles. When more than one pan is used they should be set on the same arch, each as much as its own depth higher than the other, so that the sap can be drawn, if desired, through faucets, from the highest into the lowest. If this arch is under a large shed, it will contribute much to the comfort and cleanliness of the work. Provide good dry wood.

For tapping the trees, use an auger ⅞ to ¾ inch size, and bore holes from an inch to one and a half inches deep, merely cutting through the bark and sap-wood. A deeper hole strikes into the heart-wood and begets decay. By tapping three or four feet above the ground, the sap is kept quite free from flying leaves and dirt.

Various kinds of spouts are used. Those made of tin or sheet iron are in high favor with some. They are about two inches wide and six inches long, rounded up eaves-trough fashion, and one end sharpened with a file, or on a grindstone. It is then driven into the bark just below the auger-hole, using a wooden mallet for driving, to avoid battering it. Others prefer wooden spouts, made of pine or hard wood.

Buckets are sometimes made of tin, others of pine, and others of cedar, the wooden ones being hooped with iron or ash, and painted. These are suspended either on the end of the spout (bad practice), or upon a large nail or hook driven into the tree.

For collecting sap, some still practice carrying the buckets by hand to the kettles or pans; some conduct it by shallow troughs to a large reservoir at the center of the bush. Others collect the sap by pailfuls; in a cask or vat drawn upon a sled or stone-boat.

Sugaring Off.—This is an easy process. When the sap is boiled down to a syrup, strain it through a clean flannel strainer into a medium sized cauldron, and boil it until it granulates. If leaves, pieces of bark, ashes, flies, or dirt of any kind has fallen into the sap, it must be clarified. This can be done by using milk, or saleratus and the whites of eggs. A good recipe is a half tea-cup of new milk to every pailful of syrup. Then boil slowly and stir well together, skimming off the scum which will soon rise to the surface. This done, and the syrup being found "dry" enough (by testing a little in a saucer) to make into forms, pour it into tin molds of any convenient size or form, and when solid, lay the cakes upside down to prevent premature draining. At the first leisure moment, lay the cakes on their edges with dishes underneath to catch the drainings. The cakes will soon harden.

A practice of tapping maples with the ax, hatchet and gouge, is in some sections alarmingly prevalent. It is certain ruin to any maple grove, and the price of sugar at the present time should convince farmers of the great value of a good sugar bush. In a recent letter to the *Agriculturist*, a farmer of Florence, Ohio, writes, deploring this waste, and describes the common "tap" used by himself and others. Here is a drawing of the simple implement, with his description: "Take first quality, straight grained, inch pine boards, cut them in foot lengths, and

split them up into one inch square pieces. Two inches from one end saw half-way through, and split off the ten-inch piece. Bore a quarter inch hole into the larger end, lengthways of the tap, and cut a groove from the hole to the other end. In the absence of a vise, to hold the stick to prevent splitting, burn the hole out with a hot iron. To fit them, bore a ½ inch hole in a hard wood block, and whittle down the square ends of the taps, just to fit, but not to enter it. When driven into the trees, they should hold fast when inserted an eighth to a quarter inch only; if driven in deeper, they cut off, in part, the flow of sap.

It is a good practice to deepen the holes in the trees by several successive borings during the sap season, in order thus to clear out the mold, and keep the holes sweet and pure; but never sink a hole deeper than two inches; no increased flow of sap is gained. A three-quarter inch hole will often close up almost entirely in one season.

*An "arch" in sugar-boiler's phrase means simply brick or stone-work to support boilers, kettles or pans.

A Talk About Sorghum, or Chinese Sugar Cane—Interesting and Instructive Details of Experience.

The present high price of sugar, with the prospect of a further advance, very naturally awakens increasing interest in the cultivation of the Sorghum, or Chinese Sugar Cane plant, in the North. Very many letters of inquiry are continually coming to this office, and we shall gladly give any information we can gather and communicate. Thousands of acres were grown during 1861, and manufactured into good palatable sweetening. The crop will doubtless be increased to tens, if not hundreds of thousands of acres, the present year. It seems to be settled beyond doubt, that this plant can be profitably grown in the United States below 41° north latitude, and probably even north of 42° or 43°, in favorable situations. We shall be glad to hear from all who have tried it thoroughly (whether successfully or not,) north of 43°. Perhaps we can not do better in this number than to print some memoranda or notes taken down by one of the Editors of the *American Agriculturist*, during a recent lengthy conversation with Mr. E. A. VanMeter, who has had considerable experience, both as a cultivator, and in working it up in large quantities, for his neighbors, in Washington, Tazewell County, Ill., (lat. 40° 30'.) We have samples of the syrup produced, which are of excellent quality, and which need no purifying for ordinary table or culinary use. It is indeed free from the green or sharp taste which is so common.

MR. VAN METER'S EXPERIENCE AND OPINIONS.

The plant does well upon any good corn land, and the expense of cultivating the two crops, aside from the cost of the seed, which is inconsiderable, is the same. A rather light soil—sandy loam—other things being equal, produces juice of the greatest richness. In regard to seed, it is of the utmost importance to have pure Chinese Sugar Cane. The Imphee, in his experience, is three weeks later, and produces syrup of by no means so good quality, and less in quantity. The admixture of broom corn seed is not infrequent, and is fatal to a good crop, there being little or no sweetness in the stalks. Sorghum may be planted in hills three and a-half feet apart each way, or in drills the same distance apart—the plants standing singly eighteen inches to two feet apart, and the suckers allowed to grow. If planted in hills, five stalks are left in each, and the suckers thoroughly removed. He decidedly prefers planting in drills, and thinks that this has much to do with the good results of the crop. The seed should be planted as early as the ground can be prepared, and is fit for its reception—earlier than corn. The practice of a neighbor is to sow in an early seed bed, and transplant to the field, setting the plants two feet apart in rows, and the rows three and a-half to four feet apart. This man's syrup crystalized so readily that he was obliged to make it all into sugar, and was unable to take even a sample of his molasses to the County Fair. It is the largest, best grown, and best matured stalks that yield the most and best syrup. Some juice yields seventeen per cent. of good thick syrup, and others only ten per cent.

The crop is treated like corn until it begins to ripen, which may be known by the cane turning yellow upon the joints towards the buts, and by the blackness of the seeds. At this period it should be "bladed," or stripped of its leaves, to facilitate perfect ripening. To effect the "blading," take a hickory stick, one-and-a-half to two inches in diameter and three feet long, slip on a rug, or bind it strongly within fourteen inches of the end; split this end in the middle, and spread the ends two inches apart, by a wedge in the split. This saves a great amount of labor—a single blow usually blading a stalk, and often more than one, perfectly. The blades thus removed are considered equal to corn fodder, not having been touched by the frost, and are easily cured. The bladed stalks stand after this two weeks or more, unless danger of frost makes it necessary to cut them sooner. Freezing is ruinous to the cane, giving a peculiar flavor to the syrup, and causing fermentation in the cane itself, unless pressed immediately. It must, therefore, be cut before any hard frosts—though light frosts, which wither the leaves, do no hurt.

When fully ripe, the cane should be cut, which operation is thus performed: Using a corn knife, strike off about three feet of the top as it stands (the length to be cut off will vary somewhat, according to the size and maturity of the cane). Then cut the cane off about eight inches from the ground, or at least above the first joint, and lay in piles or on the wagon. There will usually be suckers enough to bind the cane in bundles if it is desirable, or if it is to be hauled far. After the removal of the stalks, the seed may be collected, or fed to hogs or poultry on the ground. The canes are taken direct-

ly to the mill, or set up or laid in piles, and protected against frost by covering them with the tops, or with hay or straw,—in which condition they will keep for months.

The mill used was Hedges, Free & Co.'s two-horse mill—a good one—consisting of three rollers thirteen inches long, the largest and upper one eight inches, the others four inches in diameter; both small rollers act against the large one. From eight to thirteen canes are kept passing through the mill at once, and as the juice flows out it is conducted to the "clarifier," being as liquid as water, and of a dark grass-green color. (Implice juice is of a dark, muddy hue.) In the clarifying pan it is mixed with Root's patent "clarifyers," (a mixture of lime, soda and eggs.) After clarifying, the juice is boiled and skimmed for fifteen minutes. From this it is drawn off into the settling box, where, mixed with clay, it stands to settle, and after fifteen or twenty minutes, may be drawn off clear and limpid, into a convenient vessel, whence it is pumped up into the evaporator.

Cook's evaporator is used, in which the fire plays under an inclined pan, down which the juice is made to run, following a zig-zag course, running faster or slower, according to the inclination of the pan, or the rapidity at which it is allowed to flow in or out. Water is placed in the evaporator to begin with, and in twenty to twenty-five minutes after the juice begins to flow in at one end syrup begins to flow out at the other. By the exercise of a little care, there is no danger of burning the syrup; but the care must be constant. A uniform product is most desirable. The syrup should not be too thick, for it will not flow readily from the barrels if it is so, and this great degree of concentration is not necessary to prevent souring. The mill runs about sixty gallons an hour, and sixty gallons is a charge for the clarifier, and so about this quantity was worked at one time.

Mr. Van Meter made syrup for half the product, and found ready sale for his portion at the mill, as fast as it was made, at fifty cents per gallon, and had no end of orders which could not be filled.

One hundred gallons to the acre was about an average yield last year for land adjoining corn which yielded fifty bushels to the acre. The Sorghum syrup, at fifty cents per gallon, half going to the boiler, nets the farmer $25; while corn only sold for fifteen cents per bushel, netting $7.50 per acre.

For ourselves, we entertain no doubt that the boiler's profit will be found too great by and by, and so a still larger profit will accrue to the farmer. We have reports of crops yielding from 100 gallons to 350, or even more, per acre.

P. S.—A Sorghum Convention.—As we close this sheet, we have from a special correspondent, a report of the meeting of Sorghum Growers, at Columbus, Ohio, Jan. 7, but cannot now find room for it. They appear to have had a good time, with their fifteen samples of beautiful Sorghum sugar, and "Sorghum syrup enough to float a [very] small frigate." Many reported having made 10 to 100 pounds each of sugar last year. Most, if not all, had used Cook's rocking Evaporator. There was considerable information brought out during the discussions and relations of experience. These referred more to harvesting and manufacturing than to planting, and will be in season hereafter. One point stated is important, viz.: that most of the seed now in the country is hybridized with broom corn, and is therefore deteriorated, making a new importation of seed desirable.

Tim Bunker on the Value of Muck.

"Ha'int you got most tired on't, squire?" asked Ben. Jones, as I carted along my twentieth load of muck last night.

"Guess not. Why?" I replied.

"It's a mighty deal of hard work for nothing. I'd just as leeves have so many loads of snow banks in a barn yard."

"It's all moonshine about there's bein any vartu in muck. I'd jest as soon dung a field with icicles," chimed in George Washington Tucker, who gets his ideas and his drinks from Jones.

"Them's my sentiments exactly," said Jake Frink, as he met us in the road with a load of oats in bags, going down to Shadtown to market. "You see I was over persuaded one year, when the Squire bo't the hoss-pond lot, to try some of the mud that come out of the side of the road, where the pond used to be. I guess I carted a dozen load, and thought I was going to see corn stalks as big as your wrist, and ears as long as a hoe-handle. And I du declare I never could see a bit a difference where I used it."

"How much manure did you put on to the acre?" inquired Seth Twiggs as he drew a lucifer across the top of his boot, and lighted his inevitable pipe.

"Wall I made a whoppin sight that year, and slapped her on ten loads to the acre."

"Corn must 'av been skeer'd at such duin's I guess," said Seth with a twinkle in his eye that the cloud of smoke could not hide.

"Corn didn't come up well did it?" asked Seth, pursuing his catechising.

"Wall, yes, it came up, but looked mighty yaller, and didn't begin to grow much till into June, and then it was spindlin, and a great many stalks didn't have any years on 'em. It was that cold frog mud that pizened the sile."

"How much corn du you git to the acre, take it by and large, Mr. Frink?" asked Seth civilly.

"I guess about twenty bushels, on an average, some times a leetle more—and some times less."

"And how much manure do you put on to the acre?" contined Seth determined to get to the bottom of the matter.

"Wall that is jest as it happens. I allers put on all I make, be it more or less, p'raps fifty or sixty loads on to eight or nine acres of plantin. It's real dung, though, and none of your bog moss, and stuff."

"And how do you suppose Squire Bunker gits eighty bushels of corn to the acre?"

"Wall, his land allers was better than mine; and then he has more cattle to make more manure, and he buys lots of guanner and bone dust, and all the ashes folks makes in the village, and sets every boy that's big enough to run on tew legs to pickin up bones, and buys every ded hoss and rotten sheep, and murdered cat, shoe maker's parin's, old boots, ded hens, old rags, and feathers, sticks 'em into this muck, and makes manure. If a man has money 'nuff to buy carrion, he can make manure and make crops, but ye see it costs more than it comes to. And then, who wants to be runnin an opposition line to the crows! The Squire is great on dead hosses, depend on't. The crows haven't had a decent meal of vittles the last five years, the Squire's been so spry after every ded critter."

Jake Frink touched up his nag and disappeared rather suddenly after this display of his philosophy of big crops. There was, of course, some foundation in truth for his reflection upon *my* methods of making manure. But neighbor Frink displayed his own pride, as well as my humiliation, in his remarks. One would hardly think it. But Jake Frink is really above his business, and is ashamed to do what ought to be done, to make the most of the materials with in his reach to enrich his stores of manure. You see this digging muck is nasty business. You must soil your boots, and your shirt sleeves, and a splash of mud upon your shirt bosom is not uncommon. And the handling of dead horses and other diseased animals is not particularly savory. But then if a man's going to be a farmer, he musn't faint at the sight of such things, or carry a smelling bottle to keep down the stenches. Muck makes *clean* corn, yellow as gold, and the sweetest of meals, and all offal and putrid flesh in the laboratory of the soil is turned into luxuriant grass, which makes nice milk, cheese, and butter, and a plenty of it. Being a farmer, and "nothing else", as the boys say, I go in for muck and more of it every year.

You gentlemen that edit agricultural papers, attend the fairs and see almost nobody but the best farmers, who carry out your teachings, think the world is almost converted to your faith. You have been preaching about muck for a dozen years or more, and you may think that every body understands it and every body uses it, and as much as they ought to. You never made a greater mistake in the world. I tell you the millenium hasn't come yet by a long shot. I guess one half the farmers in these parts to-day, have got Jake Frink's notion about muck, and it rests upon just his sort of trial, a single experiment based on an application of ten loads of half made compost to the acre. No wonder muck is considered poor stuff.

Now I am ready to give a reason for the faith that is in me. On my old land I can not make any money at farming without manure, and carting muck is the cheapest way I can make it. Indeed I should not know what to do without swamp muck. Manure, as it is sold in towns and villages in the Northern States brings from two to three dollars a *cord* of 108 bushels. As it *brings* this price it is to be presumed that it is worth this to the cultivators who buy it. These are generally market gardeners and farmers who live within four or five miles of market. If manure is worth this to the farmer who has to cart it several miles, it is certainly worth as much, or more, to the farmer who makes it and uses it upon his own farm.

Now I claim for the muck and peat that I use, that I make a dollar upon every cord that passes through my yard and stables on its way to the plowed fields where it is turned under—reckoning its value at the lowest market price, two dollars a cord. The peat as it lies in the bed yielding no income, is entirely worthless. It can be dug and thrown upon the bank of the ditch for twenty five cents a cord. If it can lie a year, all the better, but this is not essential, as fresh stable manure will cure it without frost. It can be delivered in my yard for fifty cents a cord, but it would cost those who have to cart it half a mile or more, perhaps seventy five cents a cord, making a dollar. Dry muck in the process of mixing and curing during the Winter, would be certain to lose neither in weight nor volume. In the Spring it is worth two dollars a cord as it lies in the yard. In making compost I calculate to use about three loads of muck to one of stable manure. If I have animals enough to make a hundred cords with nothing but straw, I can make four hundred with muck.

On the muck that I am able to cure in the fields where I use it, I make a still larger profit, as I save once carting. This I cure with stable

manure that I buy from the village, and with fish, dead animals, guano, or with lime and ashes, taking care not to use these latter articles with the animal manures. If any body doubts about my estimate of muck let him come to Hookertown and see my corn bin and porkers, my root cellar and cows, and my hay mows and horse stables. Jake Frink despises a dead horse and invokes crows. I think the carcass worth a "V," and save it. There is as much difference in folks as in any thing.

Yours to command
TIMOTHY BUNKER, Esq.

Hookertown, Jan. 11th, 1862.

Carting Manure in Winter.

Farmers accomplish much more in the winter months than they formerly did. The custom of going into Winter quarters after Christmas has passed away upon many farms, to the mutual advantage of the owner of the soil, and of his laborers. The working force of the farm is continued through the whole season, and the management is so skillful that there is always something to be done that will pay. In the older States, manure making occupies a prominent place. Indeed it may be said to be the foundation of the new order of things, for without this, it would be impossible to furnish profitable employment in winter for the whole amount of labor needed in summer.

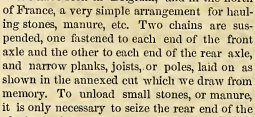
With this as the chief business, there is always work in rainy weather, in the barn cellar, or under the sheds, making compost; and the frosty weather when muck can not be dug, is improved to cart manure where it will be needed for the next season's operations. The idea that manure wastes when spread upon the surface of the meadow, or plowed field is exploded by these farmers. If the land lies level without danger of washing, they spread freely from October to May, without any apprehension of loss. The ammonia generated from the green manures is pretty well locked up in the muck with which it is mixed before it is started from the barn cellar or yards. The already fine compost is made still finer by the frosts of winter and is evenly distributed over the surface of meadows.

A very great advantage of using this season for carting, is the improved condition of the ground. The cart-way is as solid as a railroad, and almost as smooth, and a large part of the obstructions that impede the wheels is removed. The meadow is not cut up into ruts, or made rough by the hoof prints of cattle. It is much better to top dress meadows now, than to wait until Spring. It is also an advantage to cart out manure upon the fields which are to be plowed. The drawing is done more economically, it forwards the spring's work, and saves strength of team for plowing and other work that must be done in its season. JONATHAN.

How to Haul Stones and Manure.

The stone boat, or "drag," so generally used, is the most expensive method. The most that can be said in its favor is, that it is so simple in its structure that any body can make one after the planks are sawed, and that it is very convenient in loading and unloading the stones. But after the stones are loaded we want a team of elephants to draw them. It is severe on oxen by reason of the heavy strain it brings upon them. The friction upon the ground, unless covered with snow or ice, is immense. And if the ground is lubricated with frost it is a dangerous vehicle unless the surface is level, as it is very liable to run against the legs of the cattle. We have known of a fine yoke of oxen permanently disabled in this way. Stones should be moved upon wheels if we consult the welfare of our teams. A yoke of cattle will draw a ton upon broad tire wheels with about the same ease as they will draw one quarter of that weight upon a stone boat—a great saving of muscle.

For moving very large stones of five or six tuns weight, and putting them in place in a wall, there is nothing we have yet seen or heard of, quite equal to Bolles' Stone digger, (described and illustrated in the last December *Agriculturist*). But as this is somewhat expensive and not yet in general use, a very convenient carriage for stones is a platform suspended between the wheels of a wagon. The platform may be 10 to 12 feet long, and of the width of a wagon body. It may be made of strong plank, or joists, bolted or spiked upon cross-pieces. This is suspended by short stout chains from the fore and hind axles, down to within a foot of the ground, or less for a level surface. To facilitate turning, the forward end may have but one chain in the middle, which will allow the forward wheels to turn readily to the right or left. The platform may hang mainly upon the hind axle, in which case the rear may be nearly as wide as between the wheels, and the forward end run out nearly to a point. The wagon can then be turned round in a short space. The two chains on either end of the hind axle will prevent its tipping. The hind end can be tipped down to the ground for rolling on a very large stone, which can then be balanced by smaller stones thrown on in front. Such an apparatus is quickly constructed, without the aid of a mechanic, except getting the bolts from a blacksmith. Any strong wagon may be used, and much larger loads can be drawn, saving not only wear of team, but not unfrequently expense for blasting stones that could not be moved on a drag or stone-boat.

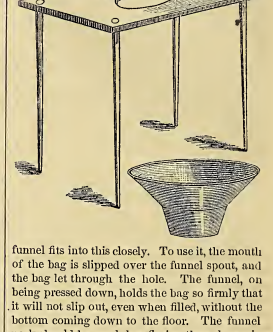


ANOTHER SIMPLE ARRANGEMENT.

We have seen in Belgium, and in the north of France, a very simple arrangement for hauling stones, manure, etc. Two chains are suspended, one fastened to each end of the front axle and the other to each end of the rear axle, and narrow planks, joists, or poles, laid on as shown in the annexed cut which we draw from memory. To unload small stones, or manure, it is only necessary to seize the rear end of the planks, which are pointed for this purpose, and lift them one by one, letting the load drop through. This plan saves lifting the whole mass of stones or manure up over the sides of a wagon. The hint is worth acting upon, and it is a wonder that we have not thought of describing it in the *Agriculturist* before now, or that some one else has not done so.

A Cheap Home-made Bag Holder.

Mr. Thomas Sheldon, of Hazardville, sends to the *Agriculturist* a description of a bag-holder of his own contrivance, which has been in use at the Hazard Powder Mills several years, for filling bags with saltpeter. It has at least the merit of being simple, easily and quickly made, and is unpatented. The accompanying sketch, made partly from the description, and partly from a penciling made by Mr. S., will show its form and operation. A board, say 14 by 24 inches, is fitted with legs of any desired length. These may be fastened like an ordinary table, or be merely rough sticks, fitted into auger holes, to be taken out at pleasure for packing away. In the center of the board a round hole is cut, say 10 inches in diameter. A tin or sheet-iron



funnel fits into this closely. To use it, the mouth of the bag is slipped over the funnel spout, and the bag let through the hole. The funnel, on being pressed down, holds the bag so firmly that it will not slip out, even when filled, without the bottom coming down to the floor. The funnel neck should be much less flaring than shown in the engraving, or it will not wedge in the bag so strongly. This would seem to be a good apparatus, costing but very little, and requiring no cash outlay, except for the funnel.

Is it the Glanders?

A young farmer writes us about a fine young horse of his, which has some symptoms of glanders, and wants to know what the real trouble is, and how to deal with it. His horse runs at the nose, has some soreness about the jaws, is feverish, loses gradually in flesh, and is disinclined to work.

These, indeed, are among the symptoms of glanders, but a horse may have them all without having the glanders. The *decisive* marks of this disease are as follows: At first, there is an increased discharge of watery matter from the nostrils, which has a little mucus mixed with it. It generally flows first from the left nostril. It is not thick and sticky, as some say, but it becomes so after passing the first stage. Now, it becomes contagious, and the infected animal should be removed to a separate barn or pasture. If the disease is not now checked, the discharge begins to contain *pus*, and the glands of the nostrils and under jaw become enlarged. The membrane of the nose becomes of a dark purplish or leaden color, and small ulcers break out upon it. At this stage, the general health of the horse begins to fail. He loses flesh, his hair becomes dry and sheds off, he has a poor appetite, an occasional cough, the discharge from the nose becomes bloody and offensive to the smell, and the breathing labored. Tumors soon appear on the face and neck, and inside of the thighs, the hind legs swell and become hot and tender, and the whole animal becoming overcharged with disease, succumbs and dies.

A simple hard cold, or catarrh, or strangles, may sometimes show itself in the form of nasal discharge, fever and loss of appetite, and swol-

len throat, but these will soon pass off, under kind treatment.

The glanders is one of the worst and most fatal of diseases. It is sometimes inherited, and at others communicated by contagion. It sometimes comes from bad stable management, especially bad ventilation. Want of regular exercise, over-work, everything that tends to break down the vitality of the horse tends to induce glanders.

The glanders is quite contagcous. As soon as it is discovered upon a horse, he should at once be put by himself. No other horse should eat from his manger, or drink from the same pail, or wear his bridle. And, worse than all, the owner of the horse sometimes contracts the same malady by handling him.

The only useful remedies are those which will build up the general health of the horse. Turn him out to pasture. Give him light work. Properly managed, a glandered horse will sometimes do moderate service for several years; but when the disease is once established, a real and permanent cure is not to be expected.

For the American Agriculturist.

Horse Coverings and Their Use.

Some good horse-men blanket their horses all the year, while others discard their use. The advocates of the former practice claim that blanketing imparts a sleek and glossy appearance to the coat, effects a saving of food by keeping up the animal heat, protects them from flies and dust, making the grooming easier, and preventing a sudden check of perspiration, which would result in colds or other diseases. Assuming that nature gives the horse sufficient protection, and that whatever increases the labor of tending him without an equivalent gain is to be avoided, too much is claimed. His coat receives an additional gloss from the blanketing, but a horse in good health, well fed and faithfully groomed, wears a coat that needs no polishing. All the food saved by blankets, I think, can be better estimated upon paper than seen in the measure. Were there material gain, it would be economy to blanket our cows and oxen.

Constantly wearing the blanket tends to make a horse sensitive, and liable to take colds. When a horse brought from a warm stable, is stripped of his thick blanket, he undergoes a sudden and great change of temperature. Such treatment seems harsh, if not cruel, at any rate quite the reverse to the course men pursue. When we go out in cold weather, we are very careful to put on extra garments, and then lay them aside while in the house. What would be said of the man who advocated wearing overcoats in the house, and going in shirt sleeves while out of doors. Precisely similar is the practice of always keeping a blanket on a horse in the stall.

As with men, so with horses, the same regimen is not applicable in the same degree to all classes. For those horses which are used only for fast driving, the constant use of the blanket may be advisable and practicable, for they stand in the stable the greater part of the day, and when taken out, they are either heavily blanketed, or their exercise is severe. It is by the owners of this class of horses that the practice is most strongly recommended. But for horses of all work, out every day in all kinds of weather, warm stalls with plenty of bedding in a warm barn are sufficient. Wide cracks between boards near the stalls are not approved means of ventilation in a New-England climate. A barn may be warm and tight, and at the same time well ventilated. The stalls should be upon the warm side of the barn, with high and tight sides, affording double protcction. Influenced by such views, some extensive owners and excellent managers of horses in this vicinity have made their stables warmer, thus dispensing with the constant use of blankets in doors.

It is in their occasional use for preventing chills and colds, that their real benefit is found. Some sort of covering is indispensable for the health and comfort of the horse, when he is made to stand exposed to cold winds; and when he returns to the stable tired and heated, the blanket should be worn until he has cooled off; then remove it, and give him a thorough rubbing down. It is important that blankets should be of ample dimensions, for while exposed to cold, in a heated condition, the muscles of the breast and legs need protection as well as the back and sides; for this purpose blankets should be wide and long enough to pass around and fasten under the breast. A light and thin covering in fly time saves the horse much torment, and frequently saves the master serious runaways and accidents. The india-rubber coverings now becoming so common with express-men and others, who are obliged to be out in all kinds of weather, can not be too highly commended. The judicious use of blankets and other coverings in the ways stated, amply repays all expense and trouble. They prolong the days of many a hard-worked horse, and save him much suffering from stiffened legs and rheumatic muscles.

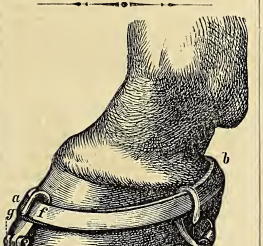

Fig. 1.

New Horse Shoes—Useful for Diseased Hoofs, and also for Instant Application in the Absence of a Blacksmith.

We have received from Germany, some accounts of a new form of horse-shoe, which would appear to be a very desirable improvement. It is patented in Austria, but, so far as we have heard, is free to the public here, and we take pleasure in presenting the accompanying engravings and description to the readers of the *American Agriculturist.* The shoe referred to is one which is applied to the hoof without the use of nails, and may be put on or taken off in a minute's time. One or more of these shoes can be carried by a person traveling, and be applied at once in case of the loss of a shoe, without waiting to reach a blacksmith's shop. They are especially adapted for use on such hoofs as will not endure the driving of nails, owing to disease, external injury, cracks or splits, brittleness, tenderness, etc., and are particularly adapted to diseases of the *sole.*

Description.—In fig. 1, a, e, represent the shoe proper. Fig. 2 shows the bottom part. The outer rim is lighter than in the common shoe, and is strengthened by the cross-bars, which also serve as a protection to the sole of the foot. There may or may not be corks at the front and

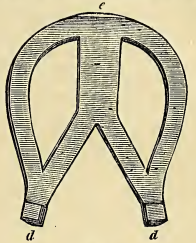

Fig. 2.

rear points. On the front and at the two sides small flat hooks are placed, which turn outwards. A strong India rubber ring or belt, (fig. 1, a, b), $\frac{3}{4}$ inch broad, and $\frac{1}{2}$ inch thick, is drawn over the hoof, and into the hooks extending up from the shoe. As the upper part of the hoof is smaller, the tendency of the rubber ring will be to slip *up*, and thus hold the shoe on firmly. To adapt the shoe to hoofs of various forms, flat or receding, as well as upright, the front hook, at g, is made with a joint. To put on or remove the shoe, it is only necessary to stretch the rubber ring sufficiently to pass it over the bottom. For very tender, diseased hoofs, care is needed not to make the rubber ring so small in diameter, or so heavy, as to pinch the hoof too strongly. As shown in our engraving, the side hooks project so as to endanger interfering. Any ingenious blacksmith can avoid this difficulty.

Look to the Sheepfold.

Sheep will not wholly take care of themselves, accommodating as they are in this respect. Lambs need special attention. In the month of September, they should be separated from their dams, and put into the best pasture the farm affords; perhaps a few old and feeble sheep may go with them. The design of this is to bring them into the wintry season fat and hearty. If under-fed in autumn, they become weak and before winter is over, many will sicken and die.

When brought into the sheep yard early in Winter, they should have, not only a daily ration of good hay, but a little grain or oil-meal beside. Of course they should have good sheds into which they can retreat in stormy weather, and where they can lie at night.

In December, let the bucks and ewes be put together. If it is desired to increase several distinct breeds, divide the ewes into as many separate lots, and put them into separate pens or yards, with a select buck in each. They will all be served in three or four weeks.

The custom of some farmers to neglect providing good fresh water for sheep, is not commendable. They can, indeed, melt snow in their stomachs, and so can all animals if compelled to do so, but good, clean water would be better. By all means, look well to the sheepfold, and especially now, when the high price of woo makes this kind of stock unusually valuable.

Burning Corn for Fuel—Will it Pay?

From recent letters received at the Office of the *American Agriculturist*, and from sundry other sources, we learn that the farmers in some parts of Illinois are using their corn as fuel, in preference to buying coal and hauling it to their farms. At first, this does not seem to exhibit a prosperous state of agriculture—and, indeed, for the present it is not, for we can hardly claim that corn can be *raised* for burning with profit. The present, however, is a disturbed time. While multitudes of men and horses are at the war, and other means of transportation imperfect, as they necessarily are in all new countries, we cannot view it as arguing anything against the profits of farming in Illinois in ordinary times, because corn is now selling at only 10 cents per bushel. And is it possible that corn can, under these circumstances, be a more economical fuel than coal? Let us see.—There are districts in Illinois, and further west, where shelled corn will sell for only 10 cents per bushel. Allowing the corn to weigh 60 pounds to the bushel, 12 pounds for the weight of cobs, and 3 pounds for cost of shelling, we have 10 cents for 75 pounds in the ears. The cost of hauling to the railroad, where say 18 cents for 75 pounds is paid, is put low enough at 8 cents, if the distance is 20 to 30 miles; but if a load of coal is brought back, only half this ought to be charged to the corn. We may then deduct 4 cents per bushel from the price of corn on the farm, to show how much it would cost, used as fuel. This is 6 cents for 75 pounds of corn on the cob, or $1 60 per ton. Corn properly dried does not contain more than 12 to 15 per cent. of water. Ordinary dry wood contains 20 per cent., or more. Therefore, 75 pounds of corn on the cob may be considered as equal at least to 60 pounds *dry* fuel—worth about $2 a ton. According to analysis, this is all combustible, except 1½ per cent. of ashes; it contains 10 per cent. of oil, and the rest is starch, gluten, and woody fiber. Its value for fuel is less per pound than that of coal, but it is doubtless worth more than the best of wood, on account of its large amount of oil. It burns very readily, and if consumed properly, analysis would indicate that it must be worth at least two-thirds as much as coal. So that, with coal costing $8 per ton, it is the cheaper fuel. This would make corn on the cob, at 18 cents per 72 pounds, after carting 20 miles, worth about as much as good hard coal, purchased at that distance from home, at $8 per ton.

There are several other circumstances to be taken into account. When only transient fires are needed, the corn would answer a better purpose than coal, but for a steady Winter fire, the coal would be preferable. Coal of poor quality would be relatively dearer. Then, again, the question turns upon the price of coal, the distance of the markets for selling corn and buying coal, the condition of the roads, the surplus team and man help, etc. All the above calculations taken into account, it is probable that in some localities, and under some circumstances, corn on the cob may be the cheapest fuel.

But there is another view of the question. Beef cattle are worth 2 cents per pound, live weight, at almost any point in the distant West. Good, fat cattle sell in New-York, even in these depressed times, for about 4½ cents per pound, live weight. The best sell for about 5 cents, and 5½ cents per pound, live weight, will pay for driving, freight, care, shrinkage, and a profit, for bringing corn-fed cattle from Iowa. The question then is, will not corn pay more than 10 cents per bushel if used for increasing the tallow and weight of cattle to be sent to Eastern markets? We think 60 pounds of corn will *add* more than 5 pounds to the weight of a bullock or steer. What say practical feeders at the West on this question? At the East, farmers feed to their beef cattle some corn, worth 50 to 70 cents per bushel, though they scarcely realize more than double the net price per pound for beef that is obtained at home by Western farmers.

(PRIZE ARTICLE.)*

On Spring Wheat.

BY EDWIN REYNOLDS—FOND DU LAC COUNTY, WIS.

THE SOIL AND ITS PREPARATION.

The *best* soil is clay loam, with a gravelly subsoil, the surface overlaid with vegetable mold such as prairie, bordering on the burr-oak openings, common at the West. All clay soils of the West will bring good wheat for three or four years without manure, but it is better not to take off more than two or three crops without manuring. Barn-yard manure made on the farm is the best general fertilizer for wheat. When the land is much worn, two bushels of lime, and three of salt to the acre, is probably the best and cheapest fertilizer that can be used. Plow in the Fall from 4 to 10 inches deep, and sow on the lime and salt in Spring. Fall plowing often brings from five to seven bushels of wheat to the acre more than Spring plowing. Deep plowing is the best, as it lets the frost deep into the soil, preparing it for a crop the coming season, and destroying many seeds and insects.

SEED.

The best varieties known in the West are the Canada Club, and Canada Fife. The Rio Grande is an excellent kind for bread, but does not yield equal to either of the above named varieties. A variety known as the China, or Australian, is being introduced and promises well; it resembles the Rio Grande. That the entire harvest may all ripen at the same time, different varieties should be sown. First the Club, second China, third Fife. The sooner wheat is sown in the Spring the surer the crop, and the better the grain—another reason why the land should be plowed in the Fall.

SELECTION AND PREPARATION OF SEED.

Many ways are practiced. The best mode is as follows: Select the best and cleanest portion of the field, and let it stand until thoroughly ripe; cut and shock until quite dry, and thrash with a flail. (Thrashing with a machine often cracks the largest and best grains and destroys their germs.) The seed, though selected as thus directed, should be carefully prepared. The best way is to procure two barrels, two corn baskets, a wash-tub or a half-barrel tub, a large dipper, and a half bushel measure; also plenty of salt, and one ounce of blue vitriol to each bushel. Place the tub in a convenient place, and a barrel on either side. Make four to six pailfuls of strong brine in each barrel, with two ounces of pulverized vitriol to the pailful. Fill the tub with brine, leaving space enough for one half bushel of wheat. Commence washing by pouring a half bushel of wheat into the tub near one side, in a small stream to prevent the grain from carrying down the lighter substances to the bottom. Skim off with the dipper and throw the skimmings into the basket placed on the right-hand barrel. Stir and skim until you have cleaned your seed perfectly, then pour the contents of the tub into the basket upon the left-hand barrel, and let it remain there until another washing is ready, when it must be thrown in a pile on the floor. Fill the tub from the barrels and keep good watch of the bottom of your barrels to see that the supply of salt and vitriol is constantly kept good, as otherwise the brine will soon become so weak that it will not float the heaviest oats. The vitriol acts as a preventive against smut, and the salt will pay its cost as a fertilizer. This work can be done in stormy weather, as the seed will take no harm by lying in the pile for a week or more. Lime may be used as a dryer, but should not be mixed with the wheat until the morning you commence sowing, as it will eat out the chit if left too long. When washing keep account of the bushels washed, measure the pile when you commence sowing so as to know how much it has swollen, deduct the foul mass in the basket, and by a little figuring you can ascertain how much it will require to the acre to use the same quantity as if dry. Seed cleansed in this manner does not require so much to the acre as when sown filth and all.

SOWING.

Should the ground be very uneven, it should be dragged down with a cultivator or thirty-tooth drag, in order that the grain may be covered evenly. Sowing with a seed drill is best, for the reason that it puts all the grain in at the same depth, whereby it all comes up at the same time, and ripens more evenly than when put in with a drag or cultivator. But all farmers are not forehanded enough to purchase a drill, and some must continue the old way of sowing. Many inventions for *sowing* have been scattered all over the country—some very good ones. I know of no better method than sowing broadcast by hand, as high winds prevail at the sowing season, and but few machines can be used in the wind to advantage.

The best method of sowing broadcast is, first to sow through with one hand then back with the other, always throwing with the wind. For instance: If the wind is blowing from the south go first to the east and throw with the right hand. Then pace off four paces or less, face about and sow to the west, shifting your bag and sowing with the left hand. The bag should be opened at the mouth by a hoop sewed into it; tie one lower corner to the mouth and sling it over the shoulder. A man can thus sow in any wind.

COVERING, HARROWING-IN, BUSHING, ETC.

A cultivator, in the form of a V, does very good work, but a still better one coming into use in these parts is, rectangular, three feet wide and eight feet long, with a cross-bar holding each tooth in its proper place, and furnished with a roller at each end. The ground should first be in a mellow, dry state; as wet, clumsy ground makes hard work for the team, and it is left in a poor condition for a crop. Sow from March 20th to April 15th, according to the lateness of the Spring.

Cultivate across the plowing, lapping one half, or use a thirty or forty tooth drag with the furrows, also lapping one half. The common practice of cross dragging will uncover more grain than it will cover up, therefore the dragging should be all done one way. To make the work complete, pass over it with a heavy roller. Where a roller can not be had, a brush drag made in the following manner, answers a very good purpose: Take a straight pole, five or six inches through, and bore holes about eighteen inches apart, into which insert bushes or small trees 10 or 12 feet long, with as branching tops as can conveniently be found. Then fasten a rope 16 or 20 feet long from one end of the pole to the other forming a bail, to the center of which attach the team. One horse can draw the drag, and a boy ten years old can drive it, and do the work. The pole mashes the lumps, and the brush whips the dirt into a fine state and leaves the field very smooth, and is better for land in a wet state than a roller.

AFTER TREATMENT AND INSECTS.

Very little is to be done after sowing a well cultivated farm. Clean out all brush or stones in the way of the reaper. Should the weather be dry, fields that were bushed may require rolling. This depends on the state of the soil. Should it appear too light and mellow, don't be afraid to put on a good heavy roller, even after the wheat is six inches high. When heading out, all oats and foul weeds should be pulled out, where it can be done without trampling down the wheat. A hooked knife attached to the end of a long pole can be used to a good purpose in cleaning fields, by walking through the dead furrows and reaching to the right and left cutting off the oats and foul stuff close to the ground, letting them fall in the grain, unless ripe enough to germinate, when they should be picked out and taken off. I know but little of insects, as nothing troubles our wheat but Chinch bugs. I know no remedy for these. Lime and salt may cure them as effectually as any thing. They evidently do not like the salt. Early sowing of the early varieties may be practiced with good success in guarding against insects of almost all sorts, the weevil excepted.

THE HARVESTING

is a very important part of wheat raising. From the time the wheat begins to turn, the farmer has much anxiety. His fields are closely watched, while he is preparing to perform the hardest work of the season. Every thing must be put in perfect order. Help must be secured, (and, what is also important, preparations be made to pay help). Wheat cut too green will shrink, and if too ripe it will shell. But there is little danger of making the mistake of cutting too green. Most wheat is cut too ripe. The earliest sown fields should be visited from day to day, the kernels examined, and as soon as the wheat is out of the milk, and fairly in the dough, cutting should commence. Wheat cut in this stage is whiter, will weigh more to the bushel, yield less bran, more and better flour, and sell better—as is well known to all who have tried the experi-

* The Committee found several very good articles among those prescated for examination. This one seems to come the nearest to the requirements of the offered Prize.—The main defect in all the essays presented is, that they dwell too much upon processes common to harvesting, securing, and thrashing all kinds of grain, and too little upon the advantages of Spring wheat, the best kinds, suitable soils and their preparation, maburing, season of sowing, etc.—CHAIRMAN OF COM.

lment. Cutting should be done with neatness and dispatch. Never purchase a reaper until you have tried the identical machine you intend to purchase. Reapers of the same manufacturer will not work equally well, therefore try different ones, until you get one that will do the work well and fast. When you have a reaper keep it in repair, and if you are not capable of doing it yourself, put it in charge of a man that is. A poor cradle, or a good one in poor repair is the greatest nuisance a farmer can have in his fields, except a poor hand. A cradler should understand keeping his cradle in good working order, for a cradle or rather its fingers want altering in changing from light to heavy grain, or from wet to dry grain. Then again the scythe may be too long so as to cut more grain than the fingers will gather; in this case cut off the point of the scythe, and if the fingers are too long serve them in the same way, otherwise they will haul in the standing grain and make hard work, and at the same time a waste. And this is not all—the grain thus pulled down will lie under the next swath and hinder the binder.

BINDING.

Poor binding spoils every thing from cutting to feeding the bundles into the thrashing machine. In binding after a cradler, while raking the swath into a sheaf, the buts should be kept against the leg and the grain slid together, instead of rolling it, so as to keep the buts even and the sheaf of its proper length. A band should be made in such a way that one part will draw across the heads in the band and hold them firm against the sheaf. Too much straw in a band is a detriment, as it can not be drawn tightly enough;—no more than fifty straws should be used. To make a stout band quickly, gripe the straw in the left hand just below the heads; divide it with the right hand; pass one half around the other and over the middle; take it in the right, near enough to the middle to clap the thumb on the heads, and thus hold them firm. Place the band over the bundle, and at the same time pass the left hand under it with the back next the ground, grasping the lower end of the band half way from the heads to the tie, and draw it under the sheaf, as near the middle as possible. As the tie in the band becomes firmly set against the sheaf, slip the hands together, holding on with the three lower fingers of the left hand, draw the end in the right hand between the thumb and forefingers of left; then tuck the ends under the thumb of the left and lay it about a little back, then clap your rake on the but of the sheaf, draw it towards you, dropping the rake off the bundle on the ground so as to catch the scatterings and pass on to the next. What I have been so long in describing can all be done in half a minute. Binding done in this way will stand the test of handling, and every farmer knows it must undergo a good deal before it reaches the thrashing machine. Just consider, Mr. Binder, how much you may hinder the operations of the harvest by slovenly binding. The sheaves must be carried together, perhaps by boys, then shocked and capped; next pitched on the wagon or cart, then pitched to the stacker on the mow, thence to the band cutter. Should only one bundle in twenty give out in passing through all these various moves, it wastes much time and grain. One man stopping to bind a bundle hinders not only himself but another man and team. It requires much time to gather up the scatterings, and these put into a stack often causes it to slide out of shape, which lets in the water and sometimes destroys a large quantity of grain. Then again the thrashing is hindered as it takes much longer to thrash loose grain than bound. A thrashing machine running at half speed hinders half the time of ten or twelve hands and eight horses, and all in consequence of a poor slovenly binder. Brother farmer, just watch your binders, and if you can't persuade them to do their work well, pay them off and let them tramp. (Provided you can get better ones.—Ed.)

SHOCKING.

Large fields of wheat are often seen thrown together; two and two, and then, in consequence of the hurry and scarcity of hands, the grain is allowed to remain for weeks, and unless a man is employed to go over the ground after every blow or rain, it must damage to a considerable extent, for the heads can not remain always lying on the ground without growing. By wetting and drying a number of times it becomes bleached, the bran shrivels, and the grain loses its vitality—called among farmers being "banged."

Grain of all kinds, and more particularly spring wheat, should be put up in round shocks and capped with a double cap. Commence by setting four bundles in a square, and then four more, one in each corner thus:

setting the buts firm on the ground and pressing the heads together. Select two smallish, long, slim bundles, break one across one arm by handfuls until the whole is broken. Then lay it on the shock, spreading the heads and but as much as possible. Then take the other bundle and slip the band well towards the but, and proceed as before, placing the heads in the opposite direction from the other, letting the heads cover the bands of the first one. Wheat shocked in this way will stand a long time, and any storm, except a hard blow, without damaging. It will dry out in a shorter time than if set two and two, for the reason that water can not penetrate any part of the shock. Wheat cut very green will cure in this way as soon as any, as any one can see that all the bands are left to the air. It will not shell as badly when handling, and is not exposed to birds and chipmunks as when set two and two. Should the grain be very ripe and dry, fourteen sheaves may as well be put in a shock as ten.

STACKING, ETC.,

requires care, skill, watchfulness and cautious judgment. The careless and slovenly manner in which stacking is often done is the cause of much loss of grain and time. Stacks thrown hurriedly and loosely together are sure to damage, unless the weather holds dry for ten or twelve days until the stacks are sufficiently settled to shed water. Farmers are often deceived in stacks, and are drawn off from a distance to work in harvest, and anxious to make as long a job as possible, "crack themselves up" as stackers; they are set to work, and the farmers knowing them to be good hands otherwise, have confidence in them, and take little notice how the work is done, and all thrashing time, lo and behold wet stacks from top to bottom, three or four hundred bushels of wheat to be kept separate and dried; then, after two or three weeks of perplexing care, and loss of time, he has that amount of damaged grain for market, which injures his reputation as a good wheat grower.

In driving to the stack, care should be had not to drive the load too near the stack or hit it, for after a stack is once started a small jog or push may cause a slide, which will create a shoulder and a leak, besides making much trouble for the stacker. Commence your stack by setting a bundle erect in the center of the ground on which you wish to build the stack, then set around it, going round and round keeping the sheaves as perpendicular as possible until you have attained a diameter of about fourteen feet; still adhering to the plunge the bottom but press the heads inward setting the buts out until the bottom will measure sixteen feet across, bringing the outside course quite flat. A few rails or boards may advantageously be used under the stack. Now commence on the outside, laying the second course upon your knee, putting your whole weight on each bundle and pressing them firmly together. The second row must be placed upon the first, covering the heads of the first and laying the buts even with the bands, if the bundles are of ordinary size and length of straw. Should the straw be long and loose, cover the heads from eight to nine inches; this will in full view pressing them firmly with the knees, and continue to go around in this way until the center is reached. Keep constantly in mind that the center must be kept full and *solid*. To effect this more perfectly, the outside rows may be laid loosely and packed a little as the center is approached, so that when the stack settles the outside courses may settle faster than the center, thus giving the buts of the outside course a downward inclination which will carry off the water perfectly. Build the stack perpendicularly four to six courses; then lay out, very slowly at first, five or six courses more; then three courses, one above the other, after which draw in, gradually at first. As soon as you commence drawing in, fill the middle fuller or pack tighter. A stack may be rounded off on the top, for convenience, and be perfectly safe from wet, by capping with hay or straw. If cradled in wet, a cap can be made of a sheaf and put on buts up. It is very inconvenient to put a sharp top on a large stack, oftentimes requiring a third hand, and the work is no better.

Should your stack become lower on one side than the other, avoid the foolish practice of laying on two courses, for by doing so you often cause a slide, but pack the lower side tighter, and the opposite looser until your stack is level, then proceed as before. The pitcher should have his mind on his work and keep a constant watch of the stacker. Care should be always taken not to throw the bundles on the outside course, after the stacker is off, and before the second course is placed upon it, for the reason that it may get a start outward, throwing the stack out of shape, so that it will settle with a shoulder and make a leak. Always throw the bundle in the most convenient way for the stacker. Never throw the second bundle until the first is disposed of. Mowing away wheat in barns I say nothing of, as it is safe in almost any way, but is done most conveniently in regular courses.

THRASHING.

Probably no work is more dreaded by the farmer than thrashing. Why it is so, I hardly know, unless for the reason that there are so many slovenly, lawless thrashers. The remarks made on running a reaper will apply to the thrashing machine. Farmers that know nothing of machinery often purchase thrashing machines and go forth with all confidence imaginable, but soon, for want of care and the requisite knowledge of their machine, it becomes rickety and badly worn. Thus dilapidated, stoppages frequently occur, making the job long and tedious. One experienced thrasher that has the faculty of keeping his machine in repair, is worth more to a farming community than six of the opposite stripe. Thrashers with good new machines are the most profitable to employ, provided they understand their business.

The farmer should have hands enough at thrashing to relieve him from any fixed position, so as to make himself a "spare hand." This gives him an opportunity to look around and see that the work is well done. Examine the straw, and see that the wheat is thrashed clean; examine the sieve and see that the wheat does not blow over in the chaff. Look to it and see that the wheat is not "bit by the cylinder, and if so order the concave lowered.

Thrashing should never be done until the stacks are through sweating. Stacks after standing one week, commence sweating and continue to sweat about two weeks, so that it is not safe to thrash until the stacks have stood for about four weeks. Wheat thrashed while sweating is sure to be damp and liable to must in the bins; but thrashed after the sweating process is over, it is better for milling than when thrashed before, from the fact that the bran is softer, and the flour is easier separated from it, thus giving a better yield, and whiter flour. Should your wheat be damp, and it be necessary to put it in bins without drying, avoid the foolish practice of putting in lime to absorb the moisture. Throw in a few stones or bricks, which will draw the moisture from the wheat, having the same effect as the lime, and leave the grain clean and smooth; which will please the miller much better than lime and rough dirty wheat. To clean it of smut forsee roll in lime for twenty four hours, which will burst the smut balls; then you can blow them out with a good mill.

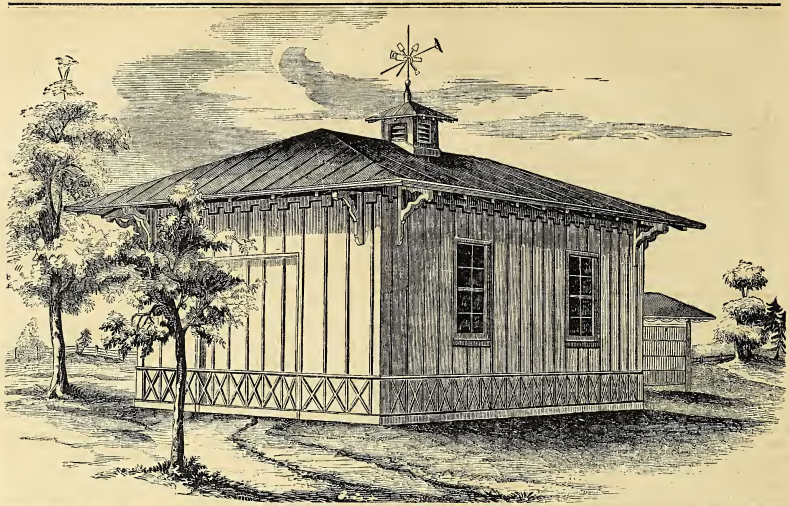
MARKETING.

Marketing wheat successfully depends very much on the locality in which the farmer is situated, and the facilities for getting to market. Obstacles are often thrown in the producers way by the grain speculator, such as raising the bids for a day or two so as to get a large quantity coming into their place of buying, and then falling down below all reason. In towns where that practice prevails, watch all their moves, and when your suspicions are strong enough to warrant it, call on the scaler of weights and measures. Still, that is of but little use, for as soon as he is gone the scales are out of balance or the measures are exchanged for others to suit the trade. Many ways are resorted to, to pilfer from the honest unsuspecting farmer. Some of these I have detected in my experience, and will mention. Every farmer that goes to market should know his own weight, and let no wheat be weighed step on the scales, see that they are balanced and weigh rightly, for scales are so constructed that a slight move will throw them in the buyer's favor—that is one practice. Again a set of false weights is sometimes kept and slipped on slyly. A sixty pound weight is sometimes placed under the large ones. The grain dealer will split a small quantity and forget to put it back. If measured, fix your eye on some mark on the half bushel so as to know it, and see that it is not changed. As soon as you discover any fraud practiced on you, have no more dealing with that man, for there are plenty of honest men in the grain business. When you find one of that character, give him all your patronage and induce as many of your neighbors as possible to go with you; and at the same time, watch him to *keep* him honest. He will pay you all he can afford to, and if another man offers you a cent or two more than he does, don't, like a blind fish, grab at the bait, for there is surely a *hook* at the end of the line.

Farmers that raise wheat enough to do so should send by the car-load, or cargo, to some commission merchant in a large commercial town, say Chicago, Milwaukee, or Buffalo, and consign his wheat to him as long as he is doing a large business, for be assured, that when a large number of his customers have left him, there is something wrong, and the less business he does the less he can afford to be strictly honest. As to the time of marketing wheat, sell when your creditors want their pay, or when you can use the money to the best advantage.

GENERAL REMARKS.

No farmer can succeed any great length of time in wheat growing by following that branch of agriculture alone. Fertilizers must be had sooner or later, and the straw alone and manure of the teams afford but a small supply. Therefore a farm of 200 acres should be so arranged as to keep at least one hundred sheep, five cows, and raise heifers enough to keep the stock of cows good. Also raise a yoke of oxen as often as once in six years. Keep a good pair of mares and from them raise, occasionally, a span of colts for market, or to remain on the farm. Six to ten swine may be fatted yearly. From that amount of stock, if the straw is properly worked in, from 200 to 250 loads of manure may be made annually. Wheat will do well and equally well on corn stubble as on plowing, if well cultivated in.



VIEW OF THE TOOL HOUSE OF TOWNSEND SHARPLESS, AT HIS SUMMER RESIDENCE IN BIRMINGHAM TOWNSHIP, CHESTER COUNTY, PENN.

A Tool House—Valuable Suggestions.

A separate place for each thing, and every thing in its place.

All ranged in order, and disposed with grace,
Shape marked of each, and each one in its place;
Nor this alone the curious eye to please,
But to be found, whene'er required, with ease.
If used or loaned, and not returned by rule,
The vacant shape will show the missing tool;
Thus often urged the careless will improve,
And rules of order soon will learn to love.

The Tool House, drawings of which are presented to the readers of the *Agriculturist*, is at the summer residence of a citizen of Philadelphia. The building is 20 feet long by 12 feet wide, and is lined with smooth boards. The engravings are exact representations of the building and its interior arrangements, with a few slight exceptions; and notwithstanding there are about 200 tools or implements upon its walls, yet the number may be considerably increased by filling up the vacant spaces with smaller articles, as there may be occasion. The tools are well secured in their places, and yet may be taken down or put up with ease. They are supported by means of nails, iron hooks of different sizes (such as are used by plumbers), stout iron staples, both flat and round, and lighter ones made of wire with the ends sharpened, and of size proportioned to the weight of the tool. *The shape of each article is marked upon the wall*, with a small stiff brush and ink, and the tools being upon the sides of the building, the floor is left free for other purposes. Their methodical arrangement, and the shape of each being distinctly marked, combine advantages as to economy of space and security against loss, which could not perhaps be so well attained by any other mode, and it is believed to be the secret of causing things to keep in their places. The writer, with whom the idea of marking out the shape originated, has had the plan in operation for many years, and always with satisfactory results; and the illustrations are presented in the hope that they may lead others to adopt this plan.

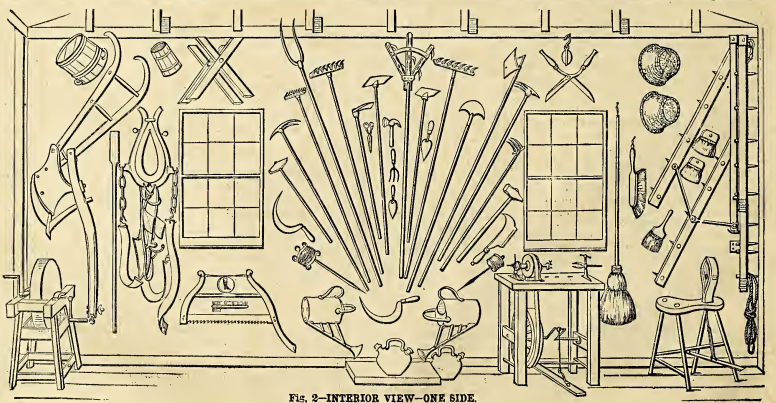


FIG. 2—INTERIOR VIEW—ONE SIDE.

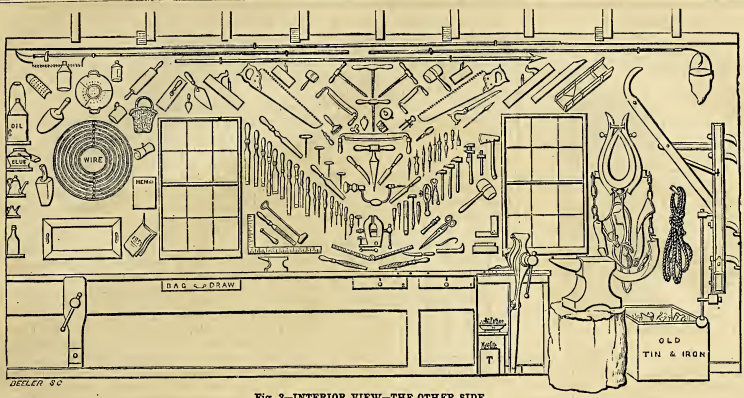

Fig. 3—INTERIOR VIEW—THE OTHER SIDE.

We need not remind the farmer how important it is that every one should have a work shop, or a substitute for one—a place where his tools may be neatly and conveniently arranged, and safely kept, and where those in his employ may occupy their leisure time pleasantly and profitably. Carefulness is often the result of early training, but indolence lies at the foundation of carelessness. Other things being equal, the careful man is generally the prosperous one, while carelessness and thriftlessness being nearly allied, always lead to loss, and frequently to disastrous results. Hence the importance of encouraging in youth habits of order, of carefulness, and of continuous useful industry.—Some borrowers are habitually neglectful in returning. Of these it has been humorously said, that "*it was trouble enough for them to borrow.*" In arranging the tools as recommended, the value of the principle of association is forcibly illustrated, and perhaps no other mode is so effectual in impressing the necessity of returning borrowed articles.

"Signs which address the ear are lost and die
In one short hour, but that which strikes the eye
Lives long upon the mind. The faithful sight
Engraves the knowledge with a beam of light."

If, therefore, when a tool is loaned, the *shape* of it is seen distinctly marked in the place from which it is taken, it will make an impression upon the mind of the borrower, which will be increased by a recollection of the fact that it will act as a tell-tale, and will not cease its importunities until its demand for the return of the article is satisfied. It requires a little effort and time to carry the plan into effect. But what that is valuable can be accomplished without effort? To the energetic mind there is a pleasure in overcoming difficulties, and any one who will adopt the plan, however rude or imperfect may be the arrangement, will find a virtue in it, in the preservation of his tools, and in promoting habits of good order beyond his expectations. Every one is an example to others for good or for evil, and he who makes even one step forward may thereby render important services in his neighborhood.

The writer would venture another suggestion. In every kind of business, there are details often neglected for want of being thought of at *the proper time*. To remedy this, it is recommended that a slate or pasteboard card, with a pencil and a piece of india-rubber attached, be hung in the shop,

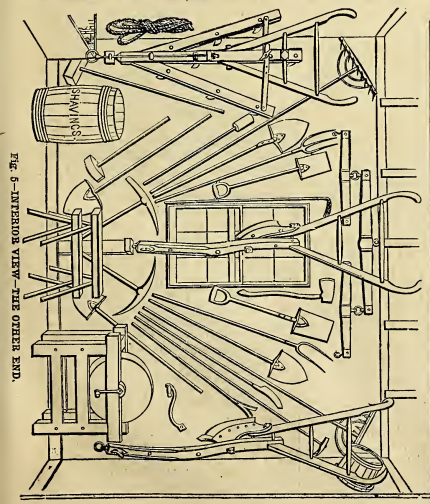

Fig. 5—INTERIOR VIEW—THE OTHER END.

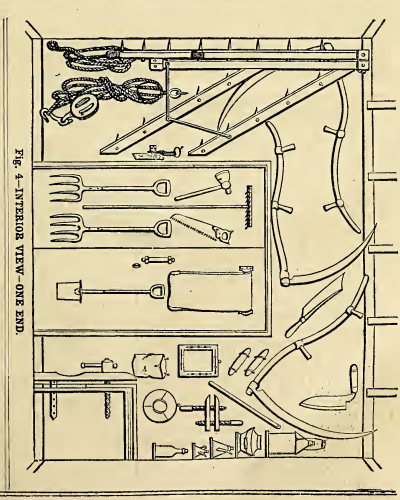

Fig. 4—INTERIOR VIEW—ONE END.

spaced and arranged under proper heads so as to show what special duties are to be performed, and by whom to be attended to when at leisure.

If the Principal would carry with him a small book, composed simply of two pieces of pasteboard,

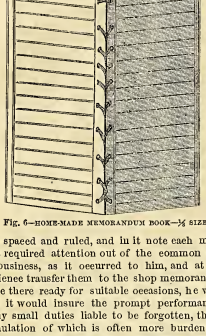

FIG. 6—HOME-MADE MEMORANDUM BOOK—¼ SIZE.

also spaced and ruled, and in it note each matter that required attention out of the common order of business, as it occurred to him, and at convenience transfer them to the shop memorandum, to be there ready for suitable occasions, he would find it would insure the prompt performance of many small duties liable to be forgotten, the accumulation of which is often more burdensome to the mind of a business man, than those of larger moment. MIQUON.

N. B.—Previous to affixing the tools to the wall, the size of the space to be occupied should be marked upon the floor, and the arrangement first made there. Some article should be selected as a starting point or centre, around which the others should be placed so as to produce a symmetrical effect. If not at first satisfactory, change the position of some, or all—arrange and re-arrange them, until they meet approval.

The ink used for making, should be a little thickened with the "grounds," and mixed upon a slate. The lines should be made dark, and on one side [*corresponding throughout the whole side*] the lines should be made much heavier than the other, to increase the effect, and add to the distinctness of shape, when the tools are absent.

Persons may make their own brushes, thus: Prepare a piece of wood about the size of a pen handle

FIG. 7—HOME-MADE MARKING BRUSH—FULL SIZE.

—then with a sharp knife make two slits in one end, the tenth or twelfth of an inch apart, and about an inch in depth. Then cut out the tongue thus formed, and fill the space with bristles (from an old brush), and secure them there by wrapping with thread. If the edges of the wood near the end are thinned, it makes a neater job. To get the bristles in nicely, cut the ends off straight, lay them crosswise in the opening, then bend them down, and wrap tight. Cut off the outside ends square, about a quarter of an inch from the stick. The brush is then complete, like the sample herewith. A little chalk rubbed over the place to be marked, will cause it to receive the ink without difficulty, and the ink will not run.

I send a sample of the book above referred to, for thy own use. It is made of French paste board, part of the lid of a glove box being peculiarly suitable. It is 6½ inches long by 3 inches wide; made in two pieces, and hinged by tape or ribbon, passed through holes in the edges, herring-bone style, thus forming a double hinge.

This book should always be carried in a suitable pocket, *inside the vest*, left hand side. The vest is most suitable, as one rarely changes that, and it leaves the coat pocket for other uses. M.

EDITORIAL REMARKS.—We are happy to have the privilege of placing before a vast multitude of readers the above communication, with the engravings, which, in part, originally appeared in a journal of only limited circulation, and were therefore not generally seen. The hints about the marking out the place of each tool back of where it is hung, are admirable. The Brush and Memorandum Book, or tablet, received, we have sketched above. They are easily made; they can be seen on our exhibition tables.

Townsend Sharpless has carried out in his business in Philadelphia the same systematic order indicated by his tool-house, and has attained eminent success. Energy, patient effort, and *systematic habits*, will seldom fail to secure success. Let us here caution the reader against turning from the perusal of this chapter with the remark, or *feeling*, that "this is all very well for the rich man, with his 200 tools, and time and money to carry out such a system." Nay, friend, the same plan is equally applicable in the barn, or out-house, or shed, (*as well as in the house,*) of the poorest farmer in the land. It is time-saving and room-saving, to have a place for the ax, hammer, saw, chisel, shovel, hoe, scythe, rake, etc., and to have their place properly indicated.

The Chestnut Tree.

For ornamental purposes, the Chestnut (*Castanea vesca,*) is hardly inferior to that monarch of the forest, the oak. Its branches ramify more loosely, and spread over a greater surface in proportion to its hight than most of the oaks. It also grows more rapidly, and in the forest it often rises ninety feet. It attains to great age, and then is of immense size. Its dark, finely cut and glossy foliage, its lofty and massy head, covered at certain seasons with golden flowered tassels, and then with clusters of fruit, render it a grand and picturesque object in the landscape. With several of the old Italian artists, it was made a favorite feature in their paintings. "This is the tree (says Gilpin,) which graces the landscapes of Salvator Rosa. The chestnut flourished in the mountains of Calabria, where he painted. There he studied it in all its forms, breaking and disposing of it in a thousand beautiful shapes, as the exigencies of his composition required."

The European varieties resemble our native tree, but have this advantage, that they remain green several weeks in Autumn, after ours have fallen into "the sere and yellow leaf." The Spanish chestnut, a very beautiful tree, is not hardy north of latitude 42°. The common American is hardy everywhere, being found, says Emerson, "on the banks of the Mousam river, Maine, above the 43d parallel of latitude, and thence southward as far as Florida, and in the western States.

The economical uses of the chestnut are not few nor unimportant. Its timber is valuable. The timber of old trees is rather loose grained and perishable, but that of the second growth is hard and durable. For posts and rails, the first being charred before setting, it makes an excellent material. By all means let the trees be felled in summer, (in what quarter of the moon we care not). This wood is sometimes used by the carpenter for inside finish. We have seen several private libraries in which chestnut wood constituted the material of the window-frames, doors, mantel pieces, and book-shelves, and being oiled and varnished, without paint, the effect was very good. In the house of a friend, thus furnished, we hardly know which to admire most, this, or the oak of his hall, or the butternut of his dining room. "In France," says Michaux, "chestnut copses are considered valuable species of property. Every seven years, they are cut for hoops, and the largest branches serve for vine-props; at the end of fourteen years, they furnish hoops for large tubs, and at the end of 25 years, they are proper for posts and light timber."

The boys and the squirrels will put in another plea for the chestnuts—they are capital things to eat! "Going a nutting," means a great deal of fun. And a peck of chestnuts bought at the corner grocery for munching, with lads and lasses around the winter fireside, means a great deal of home enjoyment.

Chestnut trees, like the oak, are hard to transplant, if taken wild from the woods. The best way is to buy them from the nurseries, where they have been several times transplanted. Or, if you are in no haste, raise them from seed yourself. Choose a rather light soil, and sow the nuts in drills. They should not be allowed to become dry before planting. Chestnuts not too dry may be planted early in Spring. Take fresh chestnuts in the autumn, mix them in a box of leaf mold and sand, and set them out of doors for the winter, guarding them, meanwhile, from mice and squirrels. In the early Spring, as soon as they begin to swell and sprout, plant them out in drills two inches deep, and a foot apart in the drills. The second year, take out every other tree, to give the remainder a better chance to grow into handsome, shapely specimens. By the second or third year, they should all be transplanted, so as to fit them for their final removal.

Garden for an Old Gentleman.

MR. EDITOR:—I lament to see so many gardens now-a-days made in such a starched up manner. Especially do I regret to see the "front-yard" spaded up and laid off into flower beds of all sorts of shapes, triangles, rhomboids and so on. Full half of these beds are very slovenly kept, and their untidiness makes a neat man nervous. But if kept ever so well, the gay colors of the flowers right before one's door, are rather exciting to an old man who loves quiet. What need of keeping folks in a state of admiring ecstacy all the time? Why not give us in front of the house and along the main walks, simply green grass, smooth as you please, and trees as fine as you please; and then place the flower borders a little one side, where we can easily visit them, and enjoy their colors and perfumes when we have a mind to? Such are the conclusions of my long experience: the readers of the *American Agriculturist* may take them for what they are worth.

I am sorry to see so many old gentlemen growing indifferent to ornamental gardening, and caring only for beets and cabbages. With me, the love of my youth and prime keeps fresh under my thin grey locks. Sometimes, I fancy that I detect fragrance less nicely than I used to, and distinguish shades of color less accurately; but there is a good deal of enjoyment left me yet; and I mean to keep my senses bright by use.

May I add a word or two of advice about the arrangement of gardens? I don't like to see a jumble of geraniums, heliotropes, verbenas, and petunias, in one small bed. The sight gives an orderly man the headache. Put each sort of plant by itself in masses; or at least, put only those together which resemble each other in size and form. Probably, the old plan of mixing up shrubs, herbaceous perennials and an-

nuals in the same bed of the flower garden will never die out—perhaps it had better not, all things considered—but would it not be well to take more pains to keep up a constant succession of blossoms in such borders? As fast as the spring bulbs bloom and fade, let early annuals be set out to fill up the gaps; and so when the biennials have had their day and gone. Keep the whole ground covered with fresh looking plants of some kind. In setting out herbaceous plants, don't stand them in straight rows, and exactly the same distance apart, like a regiment of spruce soldiers; break up the stiffness somehow.

There are two or three other things you must bear with from an old man, viz.: one word about walks, one about seats, and one about grass. You can't make your walks, my son, too hard and smooth. Of course, you will keep them clean, the verges well defined, and the curves as neatly cut as when first laid out. Some persons let the grass grow out into the gravel in one place, and then jag into the edges rudely in many other places. Preserve your lines well. Nothing gives a place such an air of finish as a good system of walks well kept. And when I visit you, let me find them hard and smooth, for I am not very sure footed of late years.

But good paths are not the only thing; they should lead to something. If they are long, there should be several resting places by the way-side, little nooks under the trees, sheltered from the sun and wind, with comfortable seats where one can sit after dinner, and read his book or newspaper, or play with his grandchildren.

Let one or more of these resting-places have good out-looks upon the surrounding country, commanding views of hills, streams, and the sky.

Now, about grass. A hay-field is a good thing in its place, very; but before a gentleman's front-door, it is *not* good. Oh! for the green, velvety lawns I saw in merry England, where I once traveled when a young man. But why not try to have good lawns in this country, be they large or small? We might have them, if young people would only set about it. Get your ground well graded at first, well tilled, well seeded down: then mow the grass often, (say once a fortnight) roll it after every shower, and you have a lawn worth the name. Give a country place good trees and smooth grass, and it will always be attractive. But I plead most earnestly for the smooth grass, for it has such an air of calm repose to an old man's eye, and such a pleasant softness to the tread of an old man's foot. SENEX.

Fungi in Cellars.

A late number of the Mark Lane Express speaks of a destructive fungus, which is doing great damage in England, especially in the wine cellars. It attacks the corks of the bottles and causes their decay—often to the destruction of their entire contents. Of a lot of Sherry bottled in 1840, the recent loss amounted to ten bottles in a hundred, and in other instances it was still greater—in one case amounting to eighty bottles in a hundred. The fungus, or dry rot, had penetrated the corks, even where covered with black mouse skin. The greatest mischief was found in cellars in which either saw dust or laths were used, the spawn of the fungus being apparently introduced with the wood or saw dust. Where either of these are used, it is recommended to first kyanize them by steeping in a solution of blue vitriol and water. But an effectual remedy would be, to seal the corks, by dipping them into melted lard and resin, of a consistency which would neither drip nor crack off. This will entirely prevent attacks from fungi, and from insects, which sometimes prove troublesome in wine vaults.

A Grape Hint.

In talking, lately, with a German vineyardist, the subject of spring and fall pruning came up. We advocated fall pruning for several reasons, and among others, this, that in autumn, the vines do not bleed, as they would in the spring.

"But," said the German, "dat ish no matter. *Let* him bleed, I *want* him bleed. If you cut off de canes in autumn, de wound dries up and hardens over." He went on to say that the drying up of the wound in autumn prevented the escape of the sap which naturally belongs in those canes, and which ought to be allowed to escape. If it can not pass off, it returns to the roots and causes them to rot.

Our friend was very earnest on this point. He insisted that for every cane cut off in autumn, a root was destroyed by excess of sap and consequent rotting. Cut off the shoots in the spring, and let the sap which has accumulated in the winter, flow off through the wounds, and no harm will come to the plant. When the excess has run off, it will stop and the wound will heal. He also maintained that fall-pruning, by checking the natural escape of sap, through several canes, caused a superabundant growth of new wood in the following summer. Prune in the spring, let the surplus sap run off, and you will get but a moderate growth of new wood.

As to fall-pruning causing rot of the roots, and premature death of the vines, we told our friend that we had seen vines so managed for a quarter of a century, and they were still in perfect health, much more so than some other vines of a neighbor which were seldom, if ever, pruned. We would thank him to *prove*, as well as assert, that fall-pruning caused rot in the roots. On the contrary, we would ask, when shoots are cut off late in Spring, does not the out-flow of sap induce a species of blight and rot upon said shoots? It certainly does on fruit and shade trees pruned at that season.

Our German friend's last argument had some more weight with us, viz.: that autumn-pruning induced a superabundant growth of wood the following season. This *fact* can not be denied. We stimulate growth by deep trenching and manuring, and then we excite it again by autumn pruning, which breaks up the balance between root and top. In reply, we hinted some objection to the deep trenching and heavy manuring recommended by some grape-growers, and we advocated a moderate pruning in mid-summer to check this overgrowth, and so save the need of severe fall pruning. Also, we said that the grand object in grape growing was to get regular and abundant crops of good fruit; and he could not deny that the prevailing system produced such results. We were tempted to hint to him that the mildew which we had often seen in his vineyard, did not speak well for his system; but we let the hint go unspoken. Still, the German's notions (which he said, were the doctrines of his countrymen in Europe,) are worthy of consideration.

How to Grow Gooseberries.

Many cultivators suffer from insects and mildew so badly, they have about given up the attempt to raise this very agreeable fruit. We suspect that a barren soil, stunting the growth of the plants, is, in many cases, the cause of the blight complained of. Another cause is the sudden alternations of temperature that occur almost every Summer. It is a mistaken notion that because the gooseberry is often found wild in poor soils, it therefore needs no manure. With the writer the treatment which ensures the best results is as follows: Give the plants a dressing of manure in the Fall, packing it in around the roots in Spring. Keep the ground clean and open until about the middle of May or first of June. Then, spread under the branches a layer of straw five or six inches thick, letting it extend over the ground as far as the roots penetrate. This mulching should remain on the ground until the first of September, when it should be removed and the soil worked clean. The design of this mid-summer dressing is to prevent any check in the growth of wood or fruit, and to keep the air about the bushes uniformly moist and cool. In this simple way, we manage to get good crops, as often as five years out of seven. Persons near the sea-side might use sea-weed or salt hay for a mulch. Tanners' bark is often used with success.

Overgrown Oleanders.

Such cases are quite common. In many a house we have seen oleanders from six to eight feet high, handsome and thrifty, but taking up too much room, and so large and cumbersome as to be moved with great difficulty. What shall be done? Just this: begin at once to raise a new plant from the old pet of the household. Take off cuttings six or eight inches long after they have done flowering next season, set them out in any shaded border of the garden, working in a little sand where they are to stand. If the wood is well ripened, eight out of every ten will make fine rooted plants in a few months.

Mushroom Spawn.

In answer to several inquirers: The mushroom seed, or "spawn," as it is usually called, is kept in the form of bricks, made of horse manure, cow dung, and loamy mold, in which a little of the spawn has been inserted, and through which it has spread. These bricks are kept on sale by the large seedsmen, at a sixpence or so each. The spawn is often found in old horse manure, in the form of small white threads running through the mass. For full directions see *Agriculturist* of last September.

NEW LARGE FLOWERING GERMAN STOCK, (J. WESLEY JONES' COLLECTION, No. 4.)
(Engraved for the American Agriculturist.)

The above engraving is as fair a representation as can be given (without the beautiful colors,) of a well-grown specimen of this plant, recently exhibited at the office of the *American Agriculturist*, by Mr. Jones of Chatham 4 Corners, N. Y. If regularity of form were indispensable in the structure of a flower, to allow it to be called beautiful, then certainly the German stock would not be admitted to that class. But fortunately, some things are beautiful that are not symmetrical. The species here represented, the *Mathiola annua*, produces more varieties than all the other species together. It is a native of the South of Europe, and is usually found growing near the sea shore. The principal varieties now in cultivation have originated in Germany, from which country we obtain our seed. This seed produces flowers ranging from the purest white to the darkest purple. To secure very early flowers, the seed should be sown in March in a hot-bed, or in a box or pot in the house. The soil in which they are sown should be finely pulverized and moderately rich. Cover the seed about one-quarter of an inch deep, and when the plants have grown an inch or so high, they should be thinned if too thick, and as much air given them as possible, but not enough to check their growth. If thinning and airing is not attended to, they are very likely to damp off, as it is termed by gardeners. As soon as the weather has become warm, they should be transplanted into the open ground, always taking a damp day for the operation if convenient. For later flowers, or general culture, sow the seeds in drills in the open ground, being careful to have the soil finely pulverized, and not to cover the seeds too deeply, or let the soil get baked or dry, as this will prevent the seeds from growing. When the plants have made their third or fourth pair of leaves, if they then stand too thickly, a portion of them should be pulled out, leaving them eight or ten inches apart. The plants thinned out may be transplanted elsewhere, with moderate care. The seeds are quite abundant. We had them in our distribution list formerly, but left them off for those more novel, or less generally to be obtained. If desired, they can come in again next year.

Chinese Wistaria—Beautiful.

One of the best perennial ornamental vines, is the Chinese Wistaria, (*Wistaria Sinensis*). It is found native in China and Japan, and when first brought to this country, was named *Wistaria*, in honor of Dr. Wistar, a well-known botanist of Philadelphia.—It is a very rapid grower, often making shoots from six to ten feet in a single summer. It blooms profusely; and, singularly, the flowers appear in the Spring before the foliage is fully developed. These flowers are quite fragrant, and appear in large, hanging masses like clusters of grapes, or more exactly, like locust blossoms six or eight inches long. Each flower in the cluster is shaped like the pea-blossom, and is of a pearly-lilac color. Last May, we noticed a vine covering a space ten by twenty-five feet, on which we counted four hundred and sixty clusters of flowers! While the plant is young, and making very rank growth, the wood is apt to die back somewhat in the Winter; therefore it should be laid down in the Fall, and covered with a little litter. When it gets well established, it is hardy enough for anybody.—There is scarcely a situation for which it is not appropriate. For town houses it answers well to cover blank walls. We have often seen it in this city, clambering up the sides of buildings, fifty or sixty feet high, twining around lightning rods and conductors, creeping along the cornice, and nodding its blooms around the garret windows. It is also a good vine for covering bowers and arbors, or the pillars of a piazza, for clothing a high fence or the trunks of trees. It is sometimes used for training to the posts and rafters of green-houses, in which places it blossoms several times a year. It may be trained into a bushy pole plant, by frequent pruning; and when so trimmed, it flowers oftener than when allowed to run. There are two other varieties, the *rosea*, and the *alba*; yes, and a third, the *violacea*, with denser racemes, variegated flowers, and with a shade of yellow, violet, and rosy purple. The last blooms later than any other species.—Plants, to begin with, can now be cheaply obtained of most nurserymen (25 to 35 cents each.) Nothing is easier than the propagation of this vine. Bend down a shoot in June, bury it three or four inches, at several buds, wounding the bark a little, and roots will soon form. But bear it in mind, not to propagate from an old shoot covered with flower-spurs: such a plant will never do well. Take a fresh, young cane, and success will be quite certain.—As an illustration of the high value put upon the Wistaria by our English friends, take the following from the London *Cottage Gardener*: "We would select the Wistaria in preference to a pillar-rose, and would prepare a border for it, as we would for a grape vine, in every particular. . . Our pillar Wistaria should be pruned exactly like a pear pyramid."

Cheap Home-made Glass Cases for Growing Plants.

"Elsie" inquires for "the cheapest possible case for growing a fern or two." The writer has somewhere seen a plan like this proposed: Take four of the largest panes of window glass you can find, bind each of them at the edges with wide linen tape, drawing the tape over the edges of the pane firmly, and sewing it down. When all have been bound, sew the ends together, four square. This will give you a glass box having neither top nor bottom. Now set out the ferns or other plants in a neat wooden box, an inch larger all around than the glass case. Set your case over this, and for a cover, lay on a pane of glass, open at the edges a trifle, to admit air.

Here is another hint: Get at the crockery-store one or more bell-glasses or shades, such as are often used for covering bouquets of artificial flowers. Then provide a flower-pot of some handsome pattern, the diameter of which is about a quarter of an inch larger than that of the glass. Now, fill the pot with sandy loam and a little leaf-mold, and set out in it one of the lycopods or lichens which are often found in green-houses. Cover the same with the glass shade, and forget not to water it occasionally. The plants will soon grow, and ere long fill the bell-glass with their fine and beautiful foliage. This is very pretty as an ornament for a lady's sewing-table in Winter. A student's window, near where we now write, is graced with one of them.

Plants Protected from Frost by Water.

Dingler's Journal (German) states, as a new discovery, that a few pails of water set among in-door plants, which are liable to injury from freezing, will protect them perfectly in quite severe weather.—This is no new discovery, but has long been practiced. Water, when passing from the liquid to the solid or frozen state, gives out a large amount of heat that was previously latent. A considerable body of water would thus keep a room sufficiently warm to prevent the destruction of many plants only half hardy. But with only a small quantity of water, or when the cold is intense, the juices or water in the fibers of the plants will congeal, and by its expansion destroy the organization, and induce disease and decay.

The Dove Flower—(*Peristeria alata.*)

Within the past few years, this beautiful plant has been admired by thousands of our countrymen while passing across the Isthmus of Panama, on their way to or from the gold fields of California. Its chief beauty consists in the form of the central portion of the flower, which resembles a white dove, with out-stretched wings, just settling into its nest of white satin. The little beak of this imaginary dove is tipped with carmine, and its wings are slightly speckled with purple. The flowers are produced on a stem two to three feet high, and continue in bloom a long time, emitting a delightful fragrance. No one, after seeing this curious plant in bloom, will wonder at the early Spanish settlers naming it Espiritú Sancta, or Holy Spirit. These fanciful and superstitious people were ready to seize upon every object, that would in any way contribute to strengthen a belief that God manifested himself to them more than to any other people. The natives of Panama, seeing the Spanish worshipping this humble plant, soon began to look upon it with veneration, and now believe there is sanctity in its very fragrance. It belongs to the family of the orchids, many of which are air plants, and is found growing in low, marshy ground, upon old decayed wood and bark mixed with earth.—A friend of ours sent us, a few years since, a dozen of the bulbs, with a box of soil in which they were found

growing. This soil was composed of decayed vegetation, mixed with a large proportion of soft stone, resembling half burned brick. The bulbs were potted in this soil, covering the lower end about one inch. They received very little water until they showed their flower stems, which was in two or three weeks, and were then watered quite freely, until they were done blooming, and the bulbs were mature, at which time water was withheld, and the bulbs were allowed their period of rest. To grow this plant successfully, requires a temperature of 85° to 95°, and a humid atmosphere.—Soft bricks, broken up into small pieces, mixed with moss and a little sandy peat, is a good soil for them. Put two or three bulbs into an eight inch pot, and keep them shaded from the direct rays of the sun. They are sold by most of the leading dealers in plants. Many keep them growing in pots of earth, on sale, at $2 to $3 each.

Newspapers Good for Bed Blankets.

The present cold weather, the high price of cotton used for quilts and "comforters," and the recent increased cost of wool adapted for blankets, all suggest to us to remind the readers of the *American Agriculturist* that common newspapers make a very good addition to the bed covering. Several papers can be pasted at the edges to form a large single sheet, to spread on the outside of a bed or even under the outside cover. The paper itself is a good non-conductor, and aids to retain much of the heat that would otherwise escape. A much more effective covering is made by placing two of the large pasted sheets together, and fastening them at the edges, and at a few other points. The thin space of air between the sheets is an admirable non-conductor. A cover of this kind is quite as effective as a closely woven woolen blanket. We have heard of an over-coat lined with paper stitched to the inside. Those who have not tried it will be surprised at the effectiveness of these bed coverings, which can be prepared in a few minutes from newspapers that would otherwise go to waste. (Of course no one would think of spoiling the *Agriculturist* by using it thus.)

For the American Agriculturist.

Hints on Dressing and Roasting a Turkey.

A turkey is one of the daintiest dishes, and in some parts of the West a commoner one than roast beef. Much, however, depends upon the manner of cooking. I well remember "fixing" my first turkey. I had had servants to do such things, until I was a woman grown, and (like other foolish girls) I never troubled myself to learn "how to stuff a turkey," until I had to do it from necessity.....When Jonathan brought home that first turkey, I was perfectly helpless, and was actually obliged to send for a neighbor to show me what to do with it. She was an old English cook, whose superior I never knew—at least so far as dressing a turkey is concerned. "It must hang up by the heels," she said, "for half an hour after the head is chopped off, for all the blood to drip out. Then lay it in a large dish pan, and saturate one half of it with water nearly boiling, and while stripping the feathers off the warm parts, have the other side down in the water heating. It should be singed before the entrails are taken out—and the flame of paper is preferable to that of straw for singing.

The stuffing—The liver, heart, gizzard, and neck, together with the sheet fat, are then washed, put down in a pot, and boiled for an hour or more, after which the meat is transferred to a chopping board, and made as fine as mince meat. The soup obtained from these parts, having been poured on the bread destined for stuffing, (stale bread is best, as it will crumble down easily), a little ground sage, pepper, and salt, with a couple of beaten eggs, are added to the mixed meat and bread, and the stuffing is ready. If the turkey has no extra fat to spare for stuffing, a piece of beef suet, about the size of a small teacup, is an excellent substitute, chopping it very fine, however.

After stuffing the turkey, sew up the apertures with a coarse needle and thread, and if the fowl is not young, parboil it before roasting. Some slices of fat beef or pork, laid under and above the turkey in the frying pan, will save the trouble of basting, and keep the meat juicy. A little water must be added to the pan from time to time, to keep the temperature below the frying point. Onion gravy is generally liked. For one cup of dripping or fat, two cups of boiling water is the allowance, together with a finely chopped onion, and two tablespoonfuls of flour. The flour better not go in until the onion is cooked. It should also be mixed with cold water. Use pepper and salt according to taste in the gravy, and also a little inside and outside of the turkey before stuffing.

Mrs. M. J. S.

Fair Haven, Ill.

"Clinker" in Stoves.

If only the first quality of coal be used, there will be little trouble from "clinker" fastening upon the sides of the stove. It is composed of various mineral impurities which are melted by the intense heat, and hardened by contact with the cooler lining of the stove. Care is needed in storing the coal in the cellar or other place, that no sand be intermixed, as this will cause clinker. The silex of which the sand is partly composed, and the potash of the ashes unite, and form a glassy substance, which adheres very tenaciously to iron or brickwork. If a stove becomes clinkered, place a few oyster shells in the fire close to the clinker. By repeating this process a few days the clinker will be loosened so as to be removed easily without breaking the lining. So says a correspondent.

Churning in Winter.

The frequent inquiries for a sure method of always churning butter as quickly and of producing as good an article in summer,as in winter, we can not well answer, for the substantial reason that we know of no such method. Good mixed feed for the cows, keeping the milk and cream from freezing, and bringing the cream to a proper temperature before beginning to churn, comprehend about all we can say on the subject. A "Subscriber," a lady, at Locust Valley, Queens Co., N. Y., communicates to the *American Agriculturist* her method of making butter in winter, which she thinks far surpasses any other plan she is acquainted with. She writes that "by this method the full quantity of butter is obtained, the quality is equal to that of grass butter, the buttermilk is rich and remains sweet for drinking, or for culinary purposes, such as making rice puddings, and the process is certain and simple, and attended with little trouble. It is as follows: The cream is skimmed each day, and placed at once in a kettle, and the kettle put into hot water (to prevent scorching), and put over the fire. The cream is allowed to scald, without boiling. It is then put into a vessel, and set aside; each day's cream being in like manner scalded, and added to the mass, until enough for a churning is obtained. The churning is commenced immediately after adding the last day's cream, which brings the whole to a proper temperature, without thinning by the addition of hot water."

More of the Corn Bread Exhibition—Fifty-four Recipes.

In January we gave a general report of the late Exhibition of Corn Bread, at the Office of the *American Agriculturist*, with the list of the exhibitors, and the directions for making the specimens of bread and cake, to which the premiums were awarded. It will be remembered that the Judges were limited by the conditions of economy, and adaptation to general use for every day diet. There were many specimens, both of corn bread and corn cake, which were superior in point of beauty and taste to those receiving the prizes, but which were not ranked first—either on account of being less economical, or less easily made, or because the specimens exhibited chanced to be not so good as would be implied by the directions, from some chance failure in the baking. But there were at least one hundred specimens which would honor any table, and would please the taste of ninety-nine persons out of every hundred. We present below the directions accompanying a considerable number of specimens, which were specially commended by the Judges. From them it will not be difficult for every family to select several kinds that will be found well adapted both to circumstances and taste. We may add here, that a number of the best loaves of bread and cake rapidly disappeared, so great was the desire of the multitude of visitors to "taste just the smallest bit." This we could have endured, though it deprived us of even a taste of them, but we found, after a time, that not only had the visitors eaten up many good loaves of bread and cake, but they had also carried off the accompanying recipes, as these were left with the several specimens. This was probably done thoughtlessly in some cases, and ignorantly in others, but it deprived others of the benefit of having the recipes published. We would respectfully solicit from the contributors another copy of the recipes accompanying the specimens, numbered in our report last month as follows: Nos. 8—11—21—39—40—44 47—60—75—121—151—158—162—167—170—171.—While we give the Committee of Judges credit for having faithfully and laboriously performed their duty, we fear that owing to the great number of specimens to be examined, some may not have received their due award of merit. Owing to our constant occupation with the visitors, and with the general oversight, we could not accompany the committee in their rounds. We append to the recipes below, in abbreviated form, extracts from the note book of the Judges. [☞ We give now all that room can be spared for. Others will be given hereafter, with some very good recipes recently received from those who did not exhibit.]

No. 1. Brown Bread.—By Mrs. D. R. Pope, Susquehanna Co., Pa. Two quarts corn meal, and 1 of rye, mixed well together, the rye to be unbolted but sifted through a common seive; add ½ pint yeast, a teacupful molasses and a little salt; pour in warm water until thoroughly wet; then dip the mixture into the baking pan; wet the hand and smooth over the top; set it in a warm place to rise; bake 2 hours. (*Com. Notes:* "Good.")

No. 3. Corn Meal Bread.—By Mrs. Louis C. d'Homergue, Middlesex Co., N. J. Recipe with cost. 1½ lbs. corn meal at 2 cts. per lb., [3 cts.]; ¼ lb. wheat flour at 3 cts. per lb. (¾ ct.]; 4 eggs at 1¼ cts. each, [5 cts.]; 1 tablespoonful butter, [½ ct.]; 2 tablespoonfuls saleratus [½ ct.]; 1 quart sour milk; total 9¾ cts. (*Com. Notes:* "Light, fine in appearance, too much alkali.—Nos. 2. and 4 by the same contributor were good and very economical.")

No. 10. Yankee Bread.—By Mrs. H. W. Ransom, Warren Co., N. Y. Two and a half pints corn meal, ½ pint flour, ½ teacupful hop yeast, 1 tablespoonful salt, 3 pints water, set 1 hour to rise; bake 2 hours. Rye flour is preferable to wheat for mixing with corn meal. (*Com. Notes:* "Good quality, but rather hard baked, and hardly light enough.")

No. 15. Rhode Island Brown Bread.—By Mrs. John R. Fales, Rhode Island. One quart coarse Indian meal, 1 pint rye flour, ⅔ cupful molasses, 1 teaspoonful each of saleratus and salt; mix with hot water, thin enough to pour. Bake 3 hours. (*Com. Notes:* "Light, well baked, sweet and good.")

No. 18. Corn Bread.—By Mrs. H. Sinclair, Monmouth Co., N. J. Scald 1 quart corn meal with sufficient boiling water to make a stiff dough; add 1 teacupful yeast, 1 teaspoonful salt; set in a warm place to rise; when light, add 2 well beaten eggs and ½ teaspoonful soda; put it in well buttered tins, and bake 1 hour. Good 3 days old. (*Com. Notes:* "Nice looking; economical, pretty good.")

No. 19. Corn Meal Buns.—By Mrs. H. Sinclair, Monmouth Co., N. J. One pint sweet milk, lump of butter size of a walnut, 1 teacupful sugar, 1 egg, 1 teaspoonful soda, 1 teacupful yeast, a little salt, spice to taste; when light, mold into cakes, with sufficient wheat flour to prevent the dough sticking to the hands. Bake 1 hour. (*Com. Notes:* "A fair article, good when hot, for breakfast or tea.")

No. 20. Corn Meal Bread.—By Mrs. H. Sinclair, Monmouth Co., N. J. To 1½ lbs. corn meal, scalded with sufficient boiling water to make a stiff dough, add 1 teacupful yeast and a little salt. Put it into a quick oven when light, and bake 1¼ hours. (*Com. Notes:* "Not of best quality, but good for an article so economical.")

No. 22. Rye and Indian Loaf.—By Mrs. C. B. Mince, New-London Co., Conn. 2¼ lbs. corn meal, 9 ounces rye meal, ½ teacupful yeast, 1 tablespoonful molasses, 1 quart skim milk, 1 quart water. Bake 3½ hours in stove. (*Com. Notes:* "Light, well baked, very good.")

No. 25. Corn Bread.—By Mrs. Lott Cornelius, Queens Co., N. Y. Into 3 quarts of skim milk, scalding hot, stir 2 quarts of new corn meal; add 1 large teaspoonful of salt, 1 of ginger, and 1 gill of molasses; greese a pan with good sweet lard, put the mixture in; make it smooth and level, pour milk over the top to prevent a hard crust, and bake 4 hours in a moderately heated oven. This like all other preparations of corn meal is decidedly better eaten hot. If to be eaten hot I would add another pint of corn meal. (*Com. Notes:* "Very cheap, and decidedly good.")

No. 32. Indian Doughnuts.—By Mrs. E. Blake, Middlesex Co., Conn. Stir 2 teacupfuls of Indian meal in 1½ cups of boiling milk. When sufficiently cooked add 2 cups wheat flour, 1 cup butter, 1½ cups sugar, 2 eggs, 1 grated nutmeg, and a little salt and yeast. Should the dough be too soft, thicken with equal quantities of meal and flour. When perfectly light, roll to ½ inch, and boil in lard. (*Com. Notes:* "Fine appearing, good, not cooked enough for corn meal.")

No. 33. Corn Bread.—By Mrs. A. O. Wilcox, New-Haven Co., Conn. To 1 pint corn meal, add 1 pint boiling water, ½ pint hop yeast, a little salt; then work in 1 pint of dry meal and wheat flour enough to mold it up, and when light add ½ teaspoonful of soda, and 1 teaspoonful cream of tartar. Bake 2 hours. (*Com. Notes:* "Good, though it appears to have been baked a little before sufficiently risen. Economical.")

No. 36. Brown Bread.—By Hannah G. Snow, Camden Co., N. J. Three pints rye meal, 1½ pints corn meal, ⅔ teacupful molasses, 1 cup yeast, 1 teaspoonful each of salt and soda; mix thoroughly with warm, but not scalding water, into a rather soft dough; set it to rise over night, bake in a slow oven 2½ hours, in iron, earthen, or tin pans—iron is best. (*Com. Notes:* "Evenly baked, light, good.")

No. 42. Corn Bread.—By S. B. Pettit, Gates Avenue, Brooklyn, N. Y. One quart milk, 6 eggs, salt, sugar to taste, 7 parts corn meal, 1 part flour, 2 ounces Durkee's Baking powder, mix dry, then mix all together. Make a stiff batter, and bake in pans 30 minutes. If no baking powder is used, use sour milk instead of sweet, and saleratus or soda. (*Com. Notes:* "Very superior. Thinish loaf,-as it should be, to be easily baked. This sample remarkably well baked.)

No. 45. Corn Cake.—By Mrs. S. J. Pine, Hauppaug, Suffolk Co., L. I. One and a half pints corn meal, ½ pint wheat flour, 2 teaspoonfuls cream of tartar, 1 teaspoonful soda, 2 eggs, ½ pint molasses, skim milk enough to make a stiff batter, flavor with nutmeg and ginger, and bake at once for about ¾ hour. (*Com. Notes:* "Decidedly good.")

No. 49. Corn Bread.—By Mrs. L. I. Prime, Queens Co., N. Y. Five cups corn meal, 1 cup wheat flour, 4 cups water, 2 tablespoonfuls sugar, 2 of yeast, and 2 tablespoonfuls of salt. (*Com. Notes:* "Very good.")

No. 50. Corn Bread.—Mrs. S. Haviland, Westchester Co., N. Y. Three teacupfuls corn meal scalded with water, ½ cup yeast made of rye flour; stir well together; set away to rise; when light, add ¾ cup wheat flour; then set away to rise again. Bake 2 hours. (*Com. Notes:* "Very good.")

No. 52. Corn Bread.—By Mrs. S. Overton, Suffolk Co., N. Y. One egg, 1 gill sugar, 1 pint buttermilk, and a little soda. Thicken with sufficient corn meal to make a stiff batter. Bake 35 to 40 minutes. (*Com Notes.* "Very good indeed.")

No. 55. Corn and Rye Loaf.—By M. A. H. Rowe, Columbia Co., N. Y. In 3 pints boiling water stir 5 pints corn meal, 1 pint rye flour, 1 cup molasses, 1 cup yeast, and 1 teaspoonful salt. Bake 1 hour, better in a brick oven, and it is well to have it remain in the oven over night. (*Com. Notes:* "A large and very fine loaf; other samples from the same source good.")

No. 59. Pumpkin Loaf.—By Mrs. C. W. Powers, Dutchess Co., N. Y. To 2 quarts Indian meal add 3 pints stewed pumpkin, while scalding hot, and work them together with a strong spoon; when cold, add ¾ pint wheat flour, 1 teacupful milk, 1 cup hot yeast, ½ cup molasses, 1 teaspoonful of salt, and stir well together. Put the mixture into a deep baking pan (iron preferable). When light, bake at a moderate heat 3 hours. If baked in a brick oven, let it stand over night, for a warm breakfast next morning. (*Com. Notes:* "Light, well baked, good. Other samples from the same source, excellent.")

No. 61. Corn Bread.—By Mrs. P. Knox, Westchester Co., N. Y. Two quarts corn meal, 1 pint flour, 3 pints buttermilk, 3 teaspoonfuls soda, 3 tablespoonfuls molasses, 2 of salt. Put the flour, meal and salt together; dissolve the soda in a little hot-water; put in the buttermilk and molasses; then mix with the hands, and bake 2 hours. (*Com. Notes:* "Light, well baked; too much soda and salt. The use of too much alkali is a common fault with the specimens on exhibition.")

No. 62. Corn Bread.—By Sarah J. Fanning, Suffolk Co., N. Y. To 3 cups corn meal, add ⅔ cups wheat flour, ½ cup yeast made of corn meal, 1 teaspoonful salt, 2 tablespoonfuls molasses. Mix with sweet milk to thick batter; let it stand until light; then bake slowly 2 hours; wrap it in a cloth wet with cold water, and let it sweat until cool. (*Com. Notes:* "Extra light, well baked, good quality.")

No. 77. Corn Cake.—By Mrs. D. G. Henry, Addison Co., Vt. Half pint Indian meal, ⅔ teacup wheat flour, 1½ cup sugar, 2 eggs, 2 spoonfuls melted butter, ½ cup cream and sour milk, ½ teaspoonful saleratus.

(*Com. Notes:* "Very good. Other samples from same contributor good also.")

No. 78. Corn Loaf.—By Adeline C. Belknap, (address not given). Two quarts corn meal, with milk enough to scald it, 1 pint wheat flour, 1 tablespoonful salt, 3 tablespoonfuls each of molasses and home-made yeast; mix well together, and let it rise about 2 hours. Bake in a slow heat, and let it stand in the oven over night. (*Com. Notes:* "Light, well baked, pretty good.")

No. 91. Corn Cake.—By Mrs. D. E. McAuley, Fairfield Co., Conn. One teaspoonful soda, ½ cup butter, 2 cups sugar, 3 cups corn meal, 4 eggs, 1 teaspoonful salt, 1 cup milk, ½ nutmeg. Bake 1½ hours. (*Com. Notes:* "Very good, well baked, remarkably light; economical.")

No. 95. Johnny Cake.—By Mrs. C. F. Moeller, Fairfield Co., Conn. Five cups corn meal, 1 cup wheat flour, 3½ cups buttermilk, 2 tablespoonfuls molasses, 1 teaspoonful salt, 1 of saleratus, a very little ginger. Bake 2½ hours, with a tin cover to prevent the crust burning. (*Com. Notes:* "Well baked, light, very good.")

No. 100. Indian Pound Cake.—By Sarah S. K. Mansfield, New-Haven Co., Conn. Take 1⅔ teacupfuls corn meal, ⅔ cup wheat flour, 2 cups sugar, 4 eggs; 1 teacupful shortening (half butter and half lard); season with nutmeg and cinnamon. Bake ¾ hour. (*Com. Notes:* "Rather too much shortening, but yet good. Corn meal, being naturally oily, no more shortening should be added than is absolutely necessary.")

No. 101. Corn Loaf.—By Dora B. Robinson, Kings Co., N. Y. Two quarts yellow corn meal, 2 tablespoonfuls melted butter, 2 teaspoonfuls salt, 2 quarts milk, or water, or an equal quantity of both, 2½ teaspoonfuls soda; mix all together and bake in a moderately quick oven 1½ hours. (*Com. Notes:* "Pretty good, but a little injured by too much soda.")

No. 103. Corn Cake.—By Mrs. R. W. Mathewson, Middlesex Co., Conn. Five cups corn meal, 1 cup wheat flour, 3 cups milk, 1 cup cream, 1 egg, a little salt, 1 teaspoonful saleratus, and 2 of cream of tartar; bake in shallow pans 1 hour. (*Com. Notes:* "Good, apparently too much cream of tartar.")

No. 105. Corn Bread.—By Mrs. J. H. Fullerton, Yorkville, N. Y. Two coffee cups sweet milk, 1 egg, 2½ coffee cups corn meal; mix well together, adding 2 teaspoonfuls cream of tartar, 1 of soda, 1 of salt, 2 tablespoonfuls molasses. (Put in the ingredients in the order named.) Bake 1 hour in a quick oven. (*Com. Notes:* "Well baked, quality good, other samples from same contributor good.")

No. 110. Corn Bread.—By Mrs. Barnes, Kings Co., N. Y. One quart corn meal, 1 quart boiling water, and a little salt. Mix and bake in shallow pans from 1 to 2 hours. (*Com. Notes:* "Cheap and good. Other samples from the same source worthy of like praise.")

No. 119. Rye and Indian Bread.—By J. G. Dennis, Newport Co., R. I. Two parts sifted corn meal, 1 part rye flour, 1 teaspoonful salt, 1 teaspoonful saleratus, 1 tablespoonful molasses; mix to a stiff dough with 1 part water to 2 parts milk. Bake slowly 5 hours. (*Com. Notes:* "Very good; recommended.")

No. 123. Corn Cake.—By Mrs. John Allison, Orange Co., N. Y. One pint thick buttermilk, (sour milk of any kind as good), 1 teaspoonful best saleratus, 3 tablespoonfuls molasses (more if preferred), 2 tablespoonfuls wheat flour, 1 pint yellow corn meal, (white will not do). Mix and bake immediately in square tins about an inch deep, with moderate fire, 1 hour or more. (*Com. Notes:* "Very good.")

No. 126. Brown Bread.—By Mary A. Castle, Herkimer Co., N. Y. Five teacupfuls corn meal, and 1 cup wheat flour wet with warm water, 1 spoon salt, ½ cup syrup, 1 pint bread sponge, to stand till light, and then to be baked with slow heat 3 hours. (*Com. Notes:* "Light, well baked, excellent.")

No. 127. Corn Meal Bread.—By Emily A. Tanner, Rockland Co., N. Y. Three gills sour milk, ⅛ ounce saleratus, ⅓ ounce salt, 2 eggs, 3 ounces wheat flour, 15 ounces corn meal. Beat the whites and yolks of the eggs separately; add the yolks to the salt; dissolve the saleratus and beat with the sour milk until it foams; then pour together and stir well; add the meal and the flour sifted; and lastly add the whites, which should be beaten to a stiff froth, stirring all the time. Pour into a buttered basin and bake 1½ hours. Estimated cost as follows: sour milk .038, saleratus .008, salt .002, eggs .266, wheat flour .056, corn meal .187—amounting to .557=total cost a fraction over 5½ cents. Weight of bread 1 lb. 10½ ounces. (*Com. Notes.* "Rather heavy, but sweet and good.")

No. 130. Corn Bread.—By Emma L. Freeman, Harlem, N. Y. One pint corn meal mixed with 2 pints cold water, stirred into 3 quarts of boiling water, to make a thin mush; add 1 tablespoonful salt and boil ½ hour; when cool stir in 4 pints corn meal, 2 tablespoonfuls molasses, and 1 yeast cake. Bake in a moderately hot oven 2½ hours. (*Com. Notes:* "All Indian meal, and good; 1-5th flour would doubtless have made it better.")

No. 131. Corn Cake.—By Emma L. Freeman, Harlem, N. Y. One quart corn meal, ½ pint wheat flour, 2½ pints warm water, 2 eggs, 1 to 2 teacupfuls molasses, 2 teaspoonfuls cream of tartar, and 1 teaspoonful each of soda and salt. Mix the cream of tarter and soda into the flour and meal; sift it all in a basin, heap it up around the sides, leaving a hole in the middle, beat the eggs very light and pour them into a basin with molasses; beat them together 5 minutes; then pour in the water and salt and stir all together well. Bake in deep pans 2 hours, in a hot stove oven. (*Com. Notes:* "Of excellent quality, but apparently not baked enough. Bread from the same contributor, good.")

No. 133. Corn Loaf.—By Mrs. R. W. Cooley, Broome Co., N. Y. One pint boiling water, 1 teaspoonful salt, 1 teaspoonful brown sugar, and a piece of butter the size of a hickory nut; let it stand till cool, which forms the yeast. Then stir in flour to make it thick; set it in a dish of warm water and stir very often until it begins to rise; then put 5 cupfuls corn meal into a pan, and add 2 teaspoonfuls salt, 1 of ginger, 3 of molasses. Pour on boiling water; sufficient to scald the meal, but not to make it thin. Let it get cold, so that it will not scald the yeast, and add 1 teacupful of the yeast and 1 of flour, and 1 teaspoonful saleratus; mix thoroughly, put into pans and bake 1 hour. The above will make two loaves, good when five days old. Would be better with more flour. (*Com. Notes:* "Very good, light, well baked, sweet.")

No. 147. Corn Bread.—By Mrs. Lucy W. Kimball, New-London Co., Conn. 1¾ lbs. corn meal, 6 oz. pork scraps, 1 teaspoonful cooking soda, ½ teacupful molasses, 1 quart sour milk, 1 teaspoonful salt; mix cold and bake. (*Com. Notes:* "Light, well baked, fair quality.")

No. 151. Corn Bread.—By Mrs. M. C. Walker, Middlesex Co., Mass. Four cupfuls corn meal, 2 cups flour, 4 cups buttermilk, 2 tablespoonfuls molasses, 1 teaspoonful saleratus, 1 of salt; bake with a moderate fire 1½ hours. N. B.—Less flour would cause the bread to crumble in cutting. (*Com. Notes:* "Light, nice, good.")

No. 152. Corn Bread.—By Mrs. M. C. Walker, Middlesex Co., Mass. Five cups corn meal, 1 cup flour, 1 cup yeast, 4 cups water, 2 tablespoonfuls molasses, 1 teaspoonful each of saleratus and salt; set to rise 5 hours, then pour into baking dish, and allow to rise again ½ hour. (*Com. Notes:* "Well baked, nice, recommended.")

No. 155. Two Corn Loaves.—By R. McDonald, Fulton Hotel, New-York City. Two lbs. corn meal, 1 lb. flour, 1 quart milk, ¼ lb. butter, ¼ lb. sugar, 2 teaspoonfuls cream tartar, 1 of soda. (*Com Notes:* "Light, well baked, very good.") We can personally endorse the committee's report that these were very good.—Ed.

No. 163. Corn Bread.—By Mrs. M. C. Turner, New-York City. Four cups meal, ½ cup flour, 2 cups water, 1 cup yeast, 1 spoonful sugar, 1 teaspoonful soda, 1 of salt. Place near the fire to rise quickly. Bake 1½ hours. (*Com. Notes:* "Very nicely baked, light, good.")

No. 164. Sweet Corn Meal Cake.—By Mrs. M. C. Turner, New-York City. One cup of sugar, 1 cup milk, 1½ cups corn meal, ½ cup flour, a piece of butter of the size of an egg, 1 teaspoonful ginger, ½ teaspoonful soda, 2 eggs. Bake ¾ hour. (*Com. Notes:* "Well baked, light, of fair quality. Other samples from same contributor good.")

No. 174. Corn Cake.—By Mrs. W***, New-York City. One quart corn meal, 1 pint milk, 4 eggs, 1 cup sugar, ½ cup butter, 1 cup stoned raisins, 1 teaspoonful salt, ½ teaspoonful mace, 1 teaspoonful cinnamon, ½ teaspoonful allspice; stir in enough meal to thicken a pint of milk, adding the butter and salt; when they are well mixed, pour into a pan, and add the sugar; when nearly cold, add the eggs and spices, and the raisins, if desired. Bake in a well buttered pan 2 hours. (*Com. Notes:* "Not quite baked enough; otherwise good. The other sample, presented by same contributor, very good.")

No. 177. Corn Bread.—By Mrs. Davis, New York City. One cup sour milk, 1 cup corn meal, 2 tablespoonfuls flour, 1 teaspoonful of sugar, ⅓ teaspoonful soda; all made in five minutes, and baked in 20 minutes. (*Com. Notes:* "Very good.")

No. 181. Corn Bread.—By E. F. P., Queens Co., N. Y. Take 2 pints of corn meal; boil one pint in a pint of water 5 minutes; when cool, add ½ pint water, 1 cent's worth of yeast, 1 teaspoonful salt, 1 pint wheat flour, and the remaining pint of corn meal; set in a warm place to rise; when sufficiently light, bake in a hot oven 1 hour. (*Com. Notes:* "A fair loaf.")

N. 184. Corn Bread.—By Mrs. L. Ryerson, Passaic Co., N. J. Two quarts corn meal, 2 quarts boiling water, 1 tablespoonful salt; mix well together and leave to cool so as not to burn the hands; then knead in with the whole of the above a yeast cake dissolved in a teacupful of warm water, and ⅔ of a pint of wheat flour; set in a warm place until small cracks appear. Bake 1¼ hours. (*Com. Notes:* "A fine loaf, only not baked quite enough.")

No. 185. Loaf of Cake.—By Mrs. L. Ryerson, Passaic Co., N. J. Two teacupfuls each of sugar and butter, mashed together; 2 eggs well beaten and mixed with the sugar and butter; 2 teacupfuls sweet milk; a heaped teaspoonful of cream of tartar; 1 even teaspoonful of saleratus, mixed in 2 teacupfuls of wheat flour, and 2 teacupfuls of Indian meal; the whole to be mixed well together and baked 1 hour. (*Com. Notes:* "Very nice.")

No. 186. Corn Bread.—By Mrs. Geo. S. Wales, Monroe Co., N. Y. To wheat bread dough enough for a loaf, when light and nearly ready to be put on the pans for the last rising, add 2 quarts of corn meal, scalded in water enough to make a stiff batter; add 1 tablespoonful salt, and 1 cupful of molasses. When cooled, mix it with the bread dough, working in at the same time rye flour enough to make it into loaves as stiff as wheat bread. Put into pans and keep in a warm place until light and ready for the oven. A slow oven is best, and a longer time is required for baking than for wheat bread. This quantity makes four loaves. (*Com. Notes:* "Light, well baked, very good.")

No. 194. Corn Bread.—By M. A. Park, Fairfield Co., Conn. Scald 3 pints of corn meal with 1 quart of milk; let it stand over night; stir in 1 cup wheat flour, 2 tablespoonfuls molasses, 1 teaspoonful salt. Bake 1½ hours. (*Com. Notes:* "A fair loaf.")

No. 195. Corn Cake.—By M. A. Park, Fairfield Co., Conn. One cup molasses, 1 cup sugar, ¾ cup butter, 3½ cups corn meal, 1 cup flour, 3 eggs, 1 pint milk, a small teaspoonful of soda; spice to taste. This makes two loaves. (*Com. Notes:* "A fine sample.")

No. 206. A Good Corn Loaf.—By Mrs. E. A. Coon, Stark Co., Ill. One quart sour milk, 2 eggs, 1 tablespoonful each of salt and lard, 1 teaspoonful soda; stir to a stiff batter with a spoon. Bake in a quick oven ¾ hour. [*Editor's Note.*—This and No. 207, came all the way from southern Illinois ("Egypt"), and arrived after the judges left. We kept them a week longer, and in our own judgment, as well as in that of many others who tried them, they were quite palatable when two weeks old. We are glad that there is "plenty of corn in Egypt," and that there is one, at least, who knows how to cook it so well. We advise others to do likewise. Anybody who would pine on Nos. 206 and 207, ought to go hungry—if not starve.]

No. 207. A Cheap Corn Loaf.—By Mrs. E. A. Coon, Stark Co,, Ill. Pour 1 quart of boiling water on a quart of corn meal; stir together, and let it stand until cool; add half a teacupful of good, sweet hop yeast, and a tablespoonful of salt. Bake in a quick oven.

No. 220. Brown Bread.—By Mrs. R. B. Neal, Tuftonboro', N. H. Three quarts Indian meal, 3 pints wheat middlings, sifted and well mixed, and 2 quarts of milk. If the weather is cold, add 1 pint of boiling water, if warm, 1 pint of the milk instead of the water, and if sweet milk is used, dissolve in it 2 teaspoonfuls saleratus or soda, but if the milk is sour, use sufficient to remove the acidity. Mix well and let it stand an hour or two before baking; then bake well, (in a brick oven, if convenient,) and it is better if left in the oven over night. This bread will keep long, and when steamed is as good as new. Yeast or yeast powders can be used instead of saleratus or soda, if preferred. The above will make one large or two small loaves, and, if properly done, can not fail to please any lover of brown bread. It has proved good for nearly twenty years. (*Rep. Notes:* "Excellent.")

"GLORIOUS WINTER."
Engraved for the American Agriculturist.

The Editor with his Young Readers.

A PRETTY LARGE COMPANY—CURIOUS FIGURES.

As the teacher of a large well-ordered school feels when he points to the group of children and says to a visitor, "These are *my* scholars," so we feel as we think of the great throng of children—boys and girls of all ages—who belong to *our* great "*Agriculturist* Family"—to *our* school. What a company! For aught we know, they are all good boys and girls—we can't think of them otherwise. Perhaps you would each feel gratified to know something of the *size* of this company to which you belong. Everybody likes to be in a large school, or on board the biggest ship where there are the most passengers. It's something to think of, as well as tell of, when one has been a participant in a grand excursion, or a great celebration. One really attaches more value to himself, and makes more effort to act worthy of his position. Well, young friends, you belong to *our* great family; you will this year look upon the same beautiful pictures (like the one above); you will all read the same pages, you will all have similar thoughts, and in many respects, you will all belong to *one* company. But how *many* are there of you who thus belong to our group? Judging from the number of households to which our paper is a constant visitor, and the average number in a house old enough to read, we suppose that far more than *Two Hundred Thousand Boys and Girls* belong to the Agriculturist Family. You, dear reader, help make up this grand company. Please consider yourself introduced to the whole, and as being one of the group....And what a group! Let's suppose only 200,000 all together, and give each one two feet square to stand in. *Hurrah!* A *twenty-acre field full*, with scarcely any room outside for our friends....Some curious thoughts are suggested as we, in imagination, look upon the grand gathering. Among all of you, there are no two just alike. Every mother could pick out her own children the moment she saw them; she would make no mistake. How is it that there is such a marked difference, when all have faces (cheeks, foreheads, chins, mouths, noses and eyes) so much alike in form and general appearance? Can you account for it? ....There are before us a hundred thousand bonnets and hoods, as many more hats and caps, as many coats or jackets, and as many girls' dresses. There are a hundred thousand pairs of boys' boots or shoes, and as many of girls shoes, and so on of other items of dress. How many stitches have been taken by the mothers of our group to make up all the dresses, and aprons, and skirts, the coats, pants, and the other garments? Can any of our girls tell how many stitches they each wear out in a year? Can any of the boys? Do you ever think who makes or pays for these stitches?....Let us look at our whole group of young readers again. They would fill two hundred good-sized churches. They would make *two thousand* Sunday schools of one hundred scholars each. If, this year, they should each learn seven verses in the Bible every week, the whole number learned would be equivalent to *seventy-two million and eight hundred thousand* verses (72,800,000)....Suppose each should make his or her parents or some one else happy once a day, how many times would there be happiness given this year?—*Answer:* Seventy-three million times!....If each of you should only once a day get vexed at something, and *fret* about it, how many "frets" would there be, just among our usually pleasant Agriculturist Family, during this present year? Oh! oh! *Seventy-three million frets!* Suppose all try and spend at least one week (say *this* week,) without fretting, or scolding, or getting vexed at all. That will blot out *fourteen hundred thousand* exhibitions of temper that do nobody else any good, but always make the fretter think less of himself or herself. Come, let's have a trial of patience for one week, beginning this hour. Please keep these black figures (**1,100,000**) before the eye, or in the mind, and each one do your part in lessening the number for *this* week. If you like the result of the experiment, perhaps you may try it of your own accord the second week...."*Pleasant words are as a honey-comb, sweet to the soul, and health to the bones.*"—So said the wise man. Not only are pleasant words "sweet to the soul" of others, but they make one's *own* soul happy. Suppose each of our two hundred thousand boys and girls use pleasant words to others—to their parents, to their brothers, or sisters, or playmates—say once a week, where they have been accustomed to use cross, or fretful, or peevish ones; they will give (and receive) "honey-comb," and "sweetness to the soul," more than a million times, this year. Dear reader, will *you* do *your* part? Will *you* try? ..."School's dismissed." The grand company will now break up, and all hasten to their homes scattered here and there all over our vast country, from Nova Scotia to California....Here's a copy of the *February Agriculturist* to take along, to be read at each fireside. We hope you will find in it something to both please and interest you. But don't forget your part of what is to be done by the twenty-acre group you have been among to-day.

Lessons worth Learning—A Proposal.

Probably most of our young readers attend some Sunday School, and learn portions of the New Testament each week. (We hope and trust that none feel themselves "too old" to go). But whether you live near enough to attend any School or not, it will be a very good exercise to thoroughly learn a few verses each week. Aside from any other benefit, the exercise will strengthen the memory, and on this account alone is very valuable. Below is a series of 52 lessons prepared at our suggestion by Dr. James Strong, S. T. D., (author of Harmony of the Gospels, etc.,) which embrace *in chronological order*, some of the leading events, parables, etc., from the Birth of Christ to the Imprisonment of Paul at Rome—a period of about 61 years. These lessons average about 7½ verses each, or 393 verses in all, and they would read well if placed together. Any one learning these in youth will have them stored in the mind indelibly. They are being adopted in many families and schools; we have circulated some thousands of copies printed in neat tabular form, and we have a large number of scholars in our own school who will learn the whole, this year. We invite all the young readers of the *Agriculturist* to join in the exercise. We can not offer premiums to all who will do so, but we will make this proposal: One year from now, (Feb. 1863,) we will print, either in the *Agriculturist*, or in a Supplement, A ROLL OF HONOR, containing the name of every one of our readers who will this year learn all the lessons in this table, and previous to Jan. 1st, 1863 send us a certificate that it is done, from the teacher, parent, or other person, who shall hear the whole recited together in December next:

TABLE OF LESSONS FOR A YEAR.

	1863.	*Subject.*	*Chapter.*	*Verses.*
1.	Jan.	1 Angels at Bethlehem	Luke ii,	8 to 14
2.	"	12 Visit of the Magians	Matt. ii,	1 to 9
3.	"	19 Christ at twelve Years of Age	Luke ii,	42 to 49
4.	"	26 The Baptist's Mission	Mark i,	4 to 11
5.	Feb.	2 Christ's Temptation	Matt. iv,	3 to 10
6.	"	9 Interview with Nicodemus	John iii,	1 to 8
7.	"	16 Christ equal with the Father	John v,	18 to 24
8.	"	23 Doctrine of the Sabbath	Mark ii,	23 to 28
9.	Mar.	2 Parable of the Sower	Matt. xiii,	3 to 9
10.	"	9 Calling of the Twelve	Mark vi,	7 to 13
11.	"	16 John's Imprisonment	Mark vi,	21 to 29
12.	"	23 Christ the Bread of Life	John vi,	26 to 33
13.	"	30 Transfiguration	Matt. xvii,	1 to 8
14.	April	6 Necessity of Child-like temper	Matt. xviii,	1 to 7
15.	"	13 Appointment of the Seventy	Luke x,	1 to 11
16.	"	20 Parable of the Good Samaritan	Luke x,	30 to 37
17.	"	27 The Lord's Prayer	Luke xi,	1 to 8
18.	May	4 Christ the Good Shepherd	John x,	1 to 7
19.	"	11 Parable of the Prodigal Son	Luke xv,	11 to 19
20.	"	18 The Lord's Supper	1 Cor. xi,	23 to 29
21.	"	25 Christ journeying to Gethsemane	Luke xxii,	39 to 46
22.	June	1 Seizure of Christ	Luke xxii,	47 to 53
23.	"	8 Peter's Denial	Luke xxii,	54 to 62
24.	"	15 Christ before the Sanhedrim	Luke xxii,	63 to 71
25.	"	22 Christ before Pilate	Luke xxiii,	1 to 7
26.	"	29 Christ before Herod	Luke xxiii,	8 to 16
27.	July	6 Christ Sentenced by Pilate	Luke xxiii,	18 to 25
28.	"	13 The Crucifixion	Luke xxiii,	32 to 38
29.	"	20 Death of Christ	Luke xxiii,	44 to 53
30.	"	27 The Sepulchre guarded	Matt. xxvii,	62 to 66
31.	Aug.	3 Resurrection of Christ	Mark xvi,	1 to 8
32.	"	10 Christ's Appearances	Mark xvi,	9 to 16
33.	"	17 The Ascension	Acts i,	6 to 12
34.	"	24 Gift of the Holy Spirit	Acts ii,	1 to 7
35.	"	31 Peter & John before Sanhedrim	Acts iv,	5 to 12
36.	Sept.	7 Community of Goods	Acts iv,	32 to 37
37.	"	14 Martyrdom of Stephen	Acts vii,	54 to 60
38.	"	21 Conversion of Paul	Acts ix,	1 to 9
39.	"	28 Conversion of Cornelius	Acts xi,	11 to 17
40.	Oct.	5 Founding of Church at Antioch	Acts xi,	19 to 26
41.	"	12 Peter delivered from Prison	Acts xii,	1 to 7
42.	"	19 Paul appointed Missionary	Acts xiii,	24 to 31
43.	"	26 Decree of Council of Jerusalem	Acts xv,	22 to 29
44.	Nov.	2 Philippi, Jailer Converted	Acts xvi,	25 to 34
45.	"	9 Paul's Preaching at Athens	Acts xvii,	22 to 28
46.	"	16 Tumult at Ephesus	Acts xix,	21 to 27
47.	"	23 Arrest of Paul at Jerusalem	Acts xxi,	27 to 35
48.	"	30 Paul begins Voyage to Rome	Acts xxvii,	1 to 8
49.	Dec.	7 Storm during Paul's Passage	Acts xxvii,	18 to 26
50.	"	14 Paul Encourages Mariners	Acts xxvii,	27 to 34
51.	"	21 Escape from the Wreck	Acts xxvii,	39 to 44
52.	"	28 Paul's Arrival at Rome	Acts xxviii,	11 to 16

N. B. Between the last column divide the verse beginning and the verse ending the lesson—both are included.

We ought to have printed this in the *January Agriculturist*, but it was not completed when that number went to press. A little extra effort will bring up the four lessons for January. While learning these lessons, it would be well to read the intervening portions of sacred history.

NOTE TO EDITORS AND SUPERINTENDENTS.—The above can be published by any editor desiring to do so—it was copyrighted merely to stop its use for speculative purposes. Superintendents can obtain neat printed copies of the above size, or those 7x9 inches, at cost of printing—say 25 cts. to $1 per 100, according to whether printed on thin or thick paper, or on cards. We have furnished a copy to every teacher and scholar in our own school.

An Interesting Coin.

Our old correspondent, "Whistler at the Plow," sends for the *Agriculturist* boys and girls, a picture of a copper coin he recently found in his field not far from New Brunswick, N. J. We find one like it in this City, at the store of a Nu-mis-mat-ist (that is a dealer in old coins and medals). He values it at a good many dollars on account of its scarcity. It is, we believe, one of the first copper coins made in this country after the declaration of Independence, in 1776. We give an engraving showing the exact size, and the embossing or raised lines and characters on the two sides. On one side are 13 bars or stripes, representing the thirteen colonies, or States, which united in the Declaration of Independence of Great Britain. On the other side, the letters USA. stand for United States of America. They are so closely united or blended as to form but one character, thus representing the *Union*. The character somewhat resembles the dollar mark, ($,) and some have given this coin as the origin of that mark. We think, however, that the $ mark had another and earlier origin.

No Boy Wholly Bad.

"I can't be good, and I won't try."—So said a boy in our hearing, the other day. He is an active, bright boy, full of fun, and nearly but not quite, half full of mischief. He is kind hearted, loves approbation, and from the bottom of his heart would like to deserve to be called a *good* boy. He is sensitive to the opinions of others, and when for the fun of the thing, or carelessly, he has committed an error and been reproved for it, his mind dwells upon the reproof so much that he has come to think that about all he does worthy of notice is bad.—A great mistake this and likely to lead to bad consequences. No one is in a more hopeless condition than he who has lost confidence in himself. Now we happen to know something of the heart of that boy. We have studied his character for months, and though he has the reputation of being a bad boy, we know he has many more good traits than bad ones, and that, if he only thought so himself, he has the ability to be one of the smartest and best boys we are acquainted with. We hope he will see this item in the *Agriculturist*, and suspect it is in part intended for him.——Perhaps, reader, you may be in a similar state of mind. Your parents and teachers may be so constantly oppressed with labor and care that they may not have the time, or discretion, to do more than tell you of your wrong deeds. But don't get discouraged. We have known and cared for many hundreds of boys and girls, in the Sabbath school, and elsewhere, and some of them were called bad by almost every body, but we never yet knew one who had not many more good traits than bad ones. It is so with you my lad, we know it is. Remember this, and think more of your good feelings and impulses, and then you will cherish these, and they will increase and grow. Pray don't fall into, or remain in that fatal error of thinking that you are *all* bad, and that therefore there is no use of your trying to be good. As your friend we tell you *it is not so!*

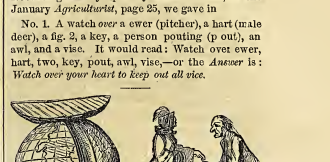
Have the Boys a Tool Chest?

Perhaps we have not said enough to encourage the boys to try to secure one of the premium Tool Chests, (See Premiums Nos. 24, 25, 26). They are really fine, and worth working for. A good many boys can yet make up a club of 28 to 43 Subscribers and they will then have a fine assortment of tools of various kinds, all arranged in a neat chest, each one in its place. They are made by Geo. Parr of Buffalo who has no little reputation as a skillful provider of tools for boys and men too. Quite a number of boys, and some men also, have already secured premium tool chests this year. Mr. Parr will get up as many more as we may need.

Rebuses.

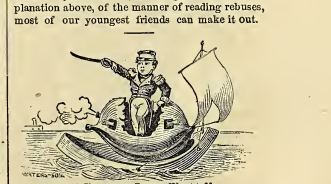
Rebuses, Puzzles, Enigmas, etc., all mean nearly the same thing—something that taxes the ingenuity to find it out. A *rebus* is generally applied to a picture puzzle, where a word or sentiment is expressed by one or more pictures. Thus, a lover painted for his sweetheart: a rose, a hill, an eye, a loaf, and a well, meaning, "Rosc Hill, I love well." Rebuses generally spell by sound. Thus, in the January *Agriculturist*, page 25, we gave in

No. 1. A watch *over* a cwer (pitcher), a hart (male deer), a fig. 2, a key, a person pouting (p out), an awl, and a vise. It would read: Watch over ewer, hart, two, key, pout, awl, vise,—or the *Answer* is: *Watch over your heart to keep out all vice.*



No. 2. This picture richly read by sound, gives one of the most beautiful passages in the Bible. Try and find it out. After trying your utmost, if then unable to read it, you can turn to Luke ii, 14. But don't be in a hurry to find the explanation.

No. 3. This picture expresses a sentiment famous in the political history of our country. We will leave you to read it, believing that after the explanation above, of the manner of reading rebuses, most of our youngest friends can make it out.



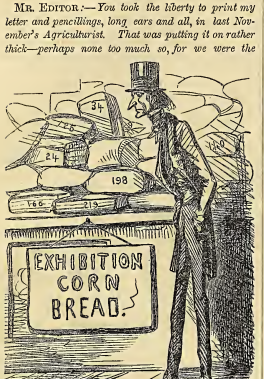
"Commodore Nutt."

Some of our *boys* doubtless feel it quite an affliction to be small, and are anxious for the time to come when they will be grown up men. We had a pleasant visit with a man the other day who will no doubt find it quite advantageous to be so *small*. Why, he is not taller than our three year old Charlie and not near so heavy. Though over 18 years old we picked him up in one hand very easily; he weighs less than half a bushel of corn. We forgot to measure him, but he will have to look *up* to see the face of Tom Thumb, certainly. Mr. Barnum has got hold of him, and he will doubtless soon be famous. He is the son of Major Nutt of Manchester, N. H., and as Barnum has had a general (Tom Thumb), he names his new protege "*Commodore*"—Commodore Nutt—perhaps also in compliment to the Navy, which appears to be reaping all the honors in the war. We commissioned our humorous artist to show up the Commodore *appropriately* in the *Agriculturist*, ahead of all others if possible.

From a Humorous Correspondent.

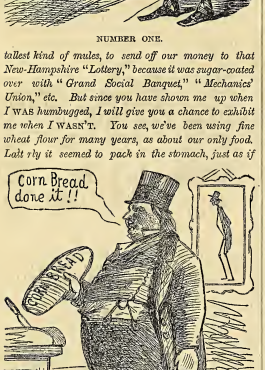
More About the Corn Bread Exhibition.

MR. EDITOR:—*You took the liberty to print my letter and pencillings, long ears and all, in last November's Agriculturist. That was putting it on rather thick—perhaps none too much so, for we were the*



NUMBER ONE.

tallest kind of mules, to send off our money to that New-Hampshire "Lottery," because it was sugar-coated over with "Grand Social Banquet," "Mechanics' Union," etc. But since you have shown me up when I WAS *humbugged, I will give you a chance to exhibit me when I* WASN'T. *You see, we've been using fine wheat flour for many years, as about our only food. Lait ry it seemed to pack in the stomach, just as if*



NUMBER TWO.

you should wet up a piece of bread, and make it into a mass of dough. When it got into the stomach, the gastric juice couldn't dissolve the lump readily; and when it did, there were no coarse particles to stimulate the digestive apparatus to action, such as Nature supplies when she makes a kernel of wheat with bran on it. The consequence was, we had the dys-pepsia very badly, wife and I had—particularly me. I frequently had to take medicine as an internal stimulant, in place of coarse particles of food. The result was, I became so thin that I often heard the boys whisper: "There goes Smith's shadow." You can see how I looked, by the sketch NUMBER ONE, *sent herewith. Well, wife and I happened down to York in December. (The fact was, our oldest daughter, who is married out West, had sent some of her best corn bread to the Exhibition, and expected the premium, and so we purposely happened there just at the right time to look after her honors.) We didn't find just what we expected: we found a great deal more, I tell you; and I wanted to come right to your desk, Mr. Editor, and tell you how surprised I was; but wife wouldn't let me—she said that if I made myself known, you would be looking after my ears, and so I kept shy of you. But, to cut my story short, wife got so interested in corn bread that she brought home lots of recipes, and has been making corn bread and corn cake for every meal since. That's only a month, and what the effect is you can see by my present portrait,* NUMBER TWO, *also sent herewith. All this comes from eating bread that don't pack in one's stomach. Perhaps a little is due to the oil or fat in the corn.*

Yours, etc.

Barnstable Co., Mass., Jan. 18, 1862.

New-York Live Stock Trade for 1861.

Accounts are kept at the Office of the *Agriculturist*, of all the receipts at the regular yards of live animals destined for slaughter, milch cows, etc. These accounts are gathered at the yards themselves, and not from newspaper reports. Our Monthly Reviews are made up from these, and we also furnish the reports of each market to some of our leading Daily and Weekly journals. The following record from our books will be interesting, and useful for future reference. If extra for each week in the year, the receipts of the different kinds of animals, and the weekly average price of all beef cattle sold. The price is in cents per pound for the estimated weight of the dressed carcasses:

WEEKLY RECEIPTS FOR 1861.

1861. Week Ending	Total Cattle.	Net Average price in cts.	Milch Cows.	Veal Calves.	Sheep & Lambs.	Live Hogs.	Total No. of kinds.
Jan. 7	3,273	8½	111	326	6,763	10,231	21,491
Jan. 14	4,208	8½	77	305	5,964	19,959	29,933

Average	4,270	7 4-5	110	630	9,950	11,262	26,182

TOTAL RECEIPTS OF LIVE ANIMALS FOR 2 YEARS.

	Beeves.	Cows.	Calves.	Sheep.	Swine.	All kinds.
1861	236,512	5,816	33,333	527,376	585,599	1,387,577
1860	226,747	7,154	46,163	514,191	310,628	1,107,883

AVERAGE WEEKLY RECEIPTS FOR 2 YEARS.

	Beeves.	Prices.	Cows.	Veals.	Sheep.	Swine.	All kinds.
1861	4,270	7 4-5	110	630	9,950	11,262	26,182
1860	4,360	8 1-5	138	772	9,888	6,147	21,305

Notes.—The second and last days of 1861 were general market days; the total receipts are really for 53 weeks. The number of beef cattle for the two years was very nearly the same, but the average business for 53 weeks in 1860, is a little higher. The net price of beef averaged 2-10ths of a cent, or 4 mills per lb. lower in 1861 than in 1860. Fewer cows were required last year, as the better pasturage secured more milk from the cows kept. The number of live hogs nearly doubled, owing to the disturbed condition of the hog-slaughtering towns along the Ohio and Mississippi rivers, and the blockade of the Mississippi, which stopped the usual shipping of pork down that channel. It will be seen by the table that for the closing weeks of the year, 18,000 to 40,000 live hogs were brought to New-York, against a weekly average of 6,147 for all of 1860. The receipts of hogs have been even larger since Jan. 1.

DERIVATION OF BEEF CATTLE.

We have gathered, weekly, the sources of the cattle brought to the Forty-fourth-street Yards, at which place were sold 192,575 of the 226,512 beef cattle brought to this City in 1861. These 192,375 came direct to the market from the following States:

Illinois	80,459	Canada	1,063
Ohio	36,554	Pennsylvania	1,053
New-York	29,052	Connecticut	805
Iowa	11,205	New-Jersey	508
Kentucky	8,189	Wisconsin	120
Michigan	4,588	Chectaw Nation	100
Missouri	3,736	Massachusetts	67
Virginia	1,417	Texas	50

N. B.—These are the points from which the cattle last came. Many cattle were brought Eastward and pastured for a season before coming to market, and were credited to the last pasture ground. This was largely the case with those set down for New-York State. From this fact, and from other sources of information, we estimate that the *great pasturing and corn-growing State of Illinois furnished more than half of all the immense supplies of beef cattle brought to New-York City during* 1861.

Figures in a Meat Bill—Interesting Items.

We give in another article a summary of the live animals brought to New-York City during 1861. These figures, with some account of the cost, etc., as prepared originally in the office of the *Agriculturist*, are being published throughout the country, generally without any credit as to their origin. We will bring together here a few items of interest. First as to the mode of selling.

BEEF CATTLE, are sold by the 'head, at a price based upon the weight of the dressed carcass. This weight averages not far from 55 lbs. for each 100 lbs. of live weight; fine fat cattle sometimes dress 60 to 65 lbs., and poorer grades run below 50 lbs. The average net price of all cattle sold in 1861 was about 7 cents and 8 mills per lb., the sales ranging from 4c. to 11c. per lb., for different grades, and at different seasons.

HOW OTHER ANIMALS ARE SOLD.—*Milch Cows*, are sold by the head, with or without the calf.—*Veal Calves*, are sold by the pound live weight.—*Sheep and Lambs* are sold at so much a head for a lot, or the pick of a lot, but the price is reported at the price per lb. live weight.—*Live Hogs*, are sold by the pound, live weight.

AVERAGE WEIGHTS AND PRICES.—*Beef Cattle:* The average net weight (dressed carcass) of all the live beef cattle sold last year was about 730 lbs. each. Average price 7 cents 8 mills per lb, or $58.40. Add to this for the offal, as below, $11.61, and we have the average price of all the cattle, large and small = $68.51.

Milch Cows: Average price for 1861 about $32.

Veal Calves: Shrinkage in killing and dressing, about 35 lbs. in the 100 lbs. Average live weight about 120 lbs., average price about 4½c. per lb.; average per head=$5.10.

Sheep and Lambs: Shrinkage in killing about 40 lbs. in 100 lbs. Average live weight of sheep about 95 lbs., and of lambs about 70 lbs.; average of all of both kinds 85 lbs., average price, 4½c.; average price per head=$3.82½.

Live Hogs: Shrinkage in killing about 22 lbs. in 100 lbs. Average live weight, 170 lbs., average price per lb. 4½c., average per head=$7.65.

BEEVES' OFFAL.—This includes Skin, Rough Tallow, Head, Tongue, Feet, Heart, Liver, Tripe, Intestines, and Manure, or strippings. All these articles are turned to account by the butcher, and are not reckoned in the carcass value, which we have put at 730 lbs., and 7 cents 8 mills per lb. The offal for last year averaged about as follows: *Skin*, average 87 lbs., average price about 5½c.=$4.78½. (The price varied during the year from 3½c. to 9c. per lb.—*Rough Tallow*, average 75 lbs., average price 7c.=$5.25.—*Heads* sold for about 25 cents each. —*Tongues* varied from 30c. to 56c. each, average say 35c. *Feet* averaged about 28c., varying from 25c. to 30c.—*Hearts* averaged about 6 lbs, and sold for only about 10 cents each.—*Livers* weigh about 10 lbs., and sold for an average of 30 cents each.—*Tripe* is nearly all used here, and is sold at an average of about 15 cents per animal.—The *Intestines* are generally stripped and used for Bologna sausages, etc., at 5 cents per animal. The *Manure*, or strippings of the tripe (stomach), and intestines, is also

sold at about 5 cents per animal. The intestines and manure are perquisites of the butcher boys. but as these are part of their pay, they should be reckoned into the value of the animal. The *total* value of the offal last year, therefore, averaged per animal, $11.61.

GENERAL SUMMARY FOR 1861.

226,312 Beef Cattle at $68.55 each	$15,513,687.60
598,509 Live Hogs at $7.65 each	4,578,593.86
527,358 Sheep and Lambs at $3.82½ each	2,037,144.35
33.388 Veal Calves at $5.10 each	170,279.80
5,816 Milch Cows at $32.00 each	186,112.00
Total (including cows)	$22,485,187.61
Total fresh Meat Bill for 1861	**$22,299,075.61**

Over Twenty-two Million Dollars for the wholesale value of live Beeves, Hogs, Sheep, and Veals, at the time of delivering from the yards. The profits while passing from the sales yards to consumers, are not taken into account. Nor does the above include all the *fresh* meat brought here. Butchers buy many animals direct from farmers, and large numbers of all kinds are brought in ready dressed, having been slaughtered elsewhere.

POUNDS OF MEAT IN THE ABOVE.

226,312 Beeves, at 730 lbs.,	dressed weight	165,208,760 lbs
598,509 Hogs, at 132 lbs.	do.	79,003,188 lbs.
527,358 Sheep, at 51 lbs.	do.	26,895,258 lbs.
33,388 Veals, at 78 lbs.	do.	2,604,264 lbs.
Total pounds of meat slaughtered		**273,711,470**

Two Hundred and Seventy-three Million Pounds of Fresh Meat in a Single Year, for this Single City of Gotham!—But these are only the animals brought in alive, and slaughtered here. It does not include the large number of animals bought by butchers daily of farmers, nor those sold from barges at the wharves, nor the immense number of dressed carcasses brought in, to say nothing of salted meats, of poultry, of game, of fish, of oysters, etc. It will be understood, however, that not all this meat is actually consumed by the million people on Manhattan Island. The neighboring cities and country, the army, and the ships, obtain much of their animal food from this City. But with these drawbacks, the slaughter going on here is wonderful—**1,387,616** animals killed here in a single year! At ten hours a day, this implies the killing of **4,448** for each working day, **445** each hour, and *more than seven for every minute!*

Market Review, Weather Notes, etc.

AMERICAN AGRICULTURIST OFFICE,
New-York, Monday Morning, Jan. 20, 1862.

*** The materials for this review are furnished specially for the *Agriculturist* by a reliable man of long experience, who, throughout the year, spends the whole of each business day in the markets, watching the transactions and collecting information, and we flatter ourselves that this report is one of the most correct anywhere published.

The preceding eleven tables, illustrative of the great movements in Breadstuffs during the year 1861, possess unusual interest for the readers of the *Agriculturist.* Having been compiled with much care and derived from authentic sources, they are perfectly reliable. We have so often and minutely referred to the heavy operations of the past year, that it is unnecessary to do more now than call particular attention to the figures here presented.

The old year closed gloomily enough, but happily the new opens with brighter prospects. Our relations with European powers, generally, and Great Britain, particularly, are now in a much more satisfactory state, and shippers begin to exhibit a renewal of confidence in the stability of the market for Breadstuffs. The uncertainty attending the legislation of Congress, in reference to taxation and currency, forms a serious impediment to the revival of activity in business. The suspension of specie payments by the Banks throws us back on a paper medium of circulation, and merchants are anxiously looking for the enactment of measures to place this on something like a reliable basis, so as to guard against the calamities which would be sure to flow from rapid fluctuations in the value of the money or the paper currency, which we are now forced to adopt, as a substitute for specie Until such time as Congress shall have made a legal provision by direct or indirect taxation, for the payment of government expenses and the public indebtedness, and thus give to the Treasury Notes and loan certificates, a permanent and reliable value, commerce will not prosper, as business men will not move freely, or be able to divest themselves of the very natural uneasiness and timidity, which they undoubtedly exhibit, at present. So far as regards our export trade in Breadstuffs, we have every reason to be satisfied with the results of each week's shipments, since the commencement of the new-year, and with the high rates at which exchange bills are selling, shippers feel disposed to continue to buy freely, if they could only be relieved from the embarrasments which they experience, as the consequence of a variable currency, fluctuating in value from day to day, and subject to serious depressions, causing very sudden and inconvenient alterations in the market for the bills of exchange which they draw against the produce they export, in order to meet their engagements with the parties of whom they purchase. The demand from the home trade is moderate. The changes in prices, during the past month, have not been very important—but a little improved for flour, as noted in the tables....There has been a lull in the market for Cotton, and serious decline in prices, in view of the expected importations from Liverpool and Bremen....The inquiry for Wool has been less active, owing in part to the firmness of holders....The trade in Provisions have been quite brisk....Moderate transactions have been reported in other commodities.

N. Y. Live Stock Markets.—THE CATTLE MARKETS have been moderately supplied during a month past—the average receipts being but 3,709, against 4,217 for the previous month. But with a largely overstocked hog market, a good supply of mutton and poultry, beeves have not advanced in price, and it was with difficulty that all were disposed of on the regular market days. Jan. 15th, with 3,668 on sale, prices ruled at 9c.@9¼c. per lb. estimated dressed weight, for a very few premium animals; 8½c.@9c. for prime; 7c.@8c. for medium to fair; 5½c.@6½c. for poor, with an average of 7¾c. for all sold, being a decline of ¼c. for the month.

Veal Calves.—Receipts for the past 4 weeks number 1,096 or 270 per week, which is less than one half of the previous month. Prices remain as last month, viz.: 5¼c.@5½c. per lb. live weight, for fat calves, and 4c.@5c. for common to good.

Sheep and Lambs.—Receipts continue to fall off, the average for the month being only 8,017 per week. Sheep sell readily at an advance upon our last quotations of fully ½c. per lb. Good fat sheep are worth prices equivalent to 5c.@5¼c. per lb. live weight, and common stock 4¾c. Dressed mutton makes up for the falling off in receipts of live stock.

Live Hogs—Immense Receipts.—The receipts have even exceeded the previously unprecedented figures of a month ago. During the past 4 weeks **147,590** live hogs have been received in this City. This is 36,897 per week. It has been impossible to find yard room for them as fast as they arrived, much less dispose of, slaughter and pack them. This keeps the market over-stocked and prices low. Jan. 15th with 46,713 hogs for the week, they sold slowly at 3⅜c.@3½c. per lb. live weight for corn-fed, and 2¾c.@3c. for still fed.

The Weather, has been somewhat variable during the past 4 weeks. Very little snow has fallen, and we have had but little really cold weather, the mercury at no time falling below 8°, above 0.——OUR DAILY NOTES, condensed, read: *December* 21, clear, cool—22, clear A. M., cloudy P. M., heavy rain at night—23, rainy day, barometer very low, viz.: 29.20, light snow at night—24, 25, clear, cool—26, cold, cloudy P. M., heavy rain at night—27, cloudy, cool—28, cold and clear—29, 30, 31, cold. ——*January* 1, clear, warm, gale of wind at night—2, 3, 4, cold—5, clear and coldest of the season, thermometer at 8°, N. E. snow at night, continuing on the 6th, making 6 inches and fair sleighing—7, clear, cool—8, mild P. M. with rain at night—9, rain A. M., clear and warm P. M.—10, light rain—11, cloudy, with 1 inch snow and sleet—12, warm and foggy, with heavy rain at night—13, clear, cool, 14, cool, with 1 inch snow at night—15, hail A. M., rain P. M.—16, clear and fine—17, cloudy—18, a northeast rain storm, which continued through the 19th, and it is still rainy on the 20th, with danger of freshets.

Rain Fall.—The rain and melted snow for a month ending Jan. 15th, amounted to 4.79 inches. About 9 inches of snow fell, during the month. The Barometer has varied more than usual, rising 1.10 inches in 36 hours and again falling quite as suddenly.

Thermometer at 6 A. M., New-York.

Observations carefully made upon a standard Thermometer (Fahrenheit.)—*r* indicates rain—*s*, snow.]

THE MAP ABOVE shows a portion of the Atlantic seaboard to which public attention is now (Jan. 20,) directed, more by guess-work than by any certain knowledge of the destination of the "Burnside Expedition." Fortress Monroe, and Norfolk, with adjacent points, are seen on the North. Sewell's Point runs up north of Norfolk, towards Fort Monroe, and defends the entrance to Norfolk. The great Inland seas or Sounds, Pamlico and Albemarle, are finely shown, with Roanoke Island between them. Also the inlets from the ocean, and the Dismal Swamp Canal, connecting the waters of Norfolk with Albemarle Sound. The Atlantic & N. C. Railroad runs northwest from Newbern, to Goldsboro', on the railroad running South from Richmond, Va., to Charleston, S. C. Weldon, N. C., on the same line, is 88 miles North of Goldsboro', and 80 miles southwest of Norfolk. Plymouth, at the head of Albemarle Sound, is equally distant southeast from Weldon, and northeast from Goldsboro'. These explanations, with this map, in connection with a school map, will aid in understanding any movement that *may* occur in the region indicated.

PREMIUM LIST,

For 1862---Vol. XXI.

Or Pay to Voluntary Agents who will attend to collecting names of new and old subscribers to the Agriculturist, and forwarding them to the Office.

Experience has proved that it is a benefit to the subscribers themselves, as well as to the Publisher, to have an *Agent* at every Post Office, to attend to collecting the names and subscriptions of old subscribers, and to present the advantages of the paper to those not yet acquainted with it. But to employ and commission a Special Agent in every neighborhood throughout the country, is out of the question. We therefore offer certain good articles, the value proportioned to the number of names sent in, and leave them open to every person disposed to attend to the business, in the locality where he or she may be known to be reliable. By giving the articles offered we can make the pay *much larger* than if in money, as we have facilities for getting the articles at low rates.

☞ In selecting articles for premiums, we have aimed to get such as are *useful*, and as have been most frequently called for by our readers. ☞ WE WISH IT DISTINCTLY UNDERSTOOD *that these premiums are offered in good faith—no cheap, trashy, imperfect, poorly made, or second-hand thing, will be sent out, but each article offered, is the best of its kind, and every one will be selected by the publisher from the very best manufactured. They will be the best sold in the market at the prices named.*

☞ We offer nothing *for competition.* Each premium is for a specified number of subscribers, and no one's remuneration will depend upon what other unknown persons are doing; every one knows just what he or she is working for.

☞ *We make no distinction between new and old subscribers*, but it is expected that every canvasser will not only gather up the names of old subscribers, but also secure a large number of new names.

☞ Every person collecting names for premiums, should send the names with the money as fast as obtained, so that the subscribers may begin to receive their papers; but if designed for premiums, two copies of each list of names should be sent—one of them marked at the top "For Premiums," and also with the name of the sender.

☞ The premiums are offered for subscribers for Volume XXI (1862), *whenever received.* Canvassers will have time for completing their lists, but the premium will be paid as soon as any club is made up—if duplicate lists are sent.

☞ Any person who has commenced sending in names at 80c. and finally fails to get the higher number of names, can fall back upon the smaller number, by remitting the 20 cents extra on each of the smaller number of names required.

☞ Clubs need not be all confined to one Post Office.

Table of Premiums for 1862.

Names of Premium Articles.	Price of Premiums.	Names at $1 each.	Names at 80 cts. each.
2—Clothes Wringer, No. 2	$7 50	18	27
3—Clothes Wringer, No. 1	$10 00	23	48
4—Sewing Machine, (Wheeler & Wilson)	$15 00	60	48
5—Sewing Machine, (Wilcox & Gibbs)	$85 00	90	120

25—Youth's Chest of Tools	$13 00	28	60
26—Gentleman's Chest of Tools	$20 00	45	80

DESCRIPTION OF THE PREMIUMS.—SEE REMARKS ABOVE.

Premiums. 2, 3.—Wringing Machine.

We place this first, for it is nearly new, and one of the most useful articles for every family. We had one of the first made, and have used it over a year with the highest satisfaction. It completely does away with the hard straining work required to wring out garments by hand. It does not twist and break the fibers of the clothes, but simply presses them between two elastic India-rubber rollers, which are moved by a crank, and whether large or small pieces, they come out dryer than when wrung by hand. The saving to garments would soon pay the cost of the implement, to say nothing of the saving of woman's labor. The machine is set upon the side of any tub; the garments drop out into a basket. A child can quickly wring out a tub full of clothes—No. 2, costing $7.50, is just the thing for common family use. This we present for 18 subscribers, at $1 each, (or 27 at the lowest club price of 80 cents each.)—No. 1, costing $10, is adapted to larger families and Hotels. We will present it for 23 subscribers at $1 each, (or 48 at 80 cts. each.)

Premium No. 4—Sewing Machine.

90 Subscribers at $1 each, (or 130 at 80 cents each,) will entitle the person sending them to *Wheeler & Wilson's* best **$45 Sewing Machine,** (including **Hemmer,**) new from the factory, and of the very best make. There is no

better family machine than this made, as we have proved by nearly *four years'* use in our own family, in connection with other machines. We want no better.—Premiums 4 and 5 will be selected new at the manufactories, be well boxed, and forwarded without expense to the recipient, except for freight after leaving the city. Full instructions sent for setting up and using.

Premium No. 5—Sewing Machine.

60 Subscribers at $1 each, (or 96 at 80 cents each,) will entitle the person procuring them to *Wheeler & Wilson's* **$125 Sewing Machines,** including a set of **Hemmers.** This is the best machine of its kind, (sewing with one thread,) and has several points superior to other machines. It is neat, well-made, simple in its operation; and having tested one in our own family for more than a year, we think highly of it, and can recommend it to those who can not afford to buy the higher priced double-thread machines.

Premium No. 6—Barometer.

19 Subscribers at $1 each, (or **44** at 80 cents each,) will entitle the person getting up the club to one of *Kendall's* **Aneroid Barometers,** (Price $7.50.) This is a good, portable instrument, and valuable to every person as a weather guide, as well as for scientific purposes. We have had one in use for nearly two years, and find it not only accurate, but an admirable weather prophet. Scarcely a rain storm or gale of wind has occurred, that has not been heralded by our barometer. Each instrument is packed in a neat leather case, 6 inches square, and 4 inches deep.

Premium No. 7—Hydropult.

30 Subscribers at $1 each, (or **48** at 80 cts. each,) will entitle the person making up the club to the **Hydropult.** (Price $12,) a very useful hand implement for carrying instantly to any desired point, to throw water from a pail, tub, cistern, or other receptacle, for extinguishing fire, watering plants, washing carriages, etc., etc. A stream can be thrown up to the third story windows. It is has jet, pipe and sprinkler; is made of brass, and is durable. It weighs 8 lbs. and can be packed in small compass to go by express or otherwise.

Premium No. 8—Melodeon.

125 Subscribers at $1 each, (or **237** at 80 cents each,) will entitle the person getting up the club to one of *Geo. A. Prince & Co's* **$170 Melodeons** (5 octaves). These Melodeons are of very superior tone and finish. We have ourselves used one for two years past, and it has given the highest satisfaction, and is pronounced by all who have heard it, as one of the very best. The different priced instruments are of equally good tone—differing only in the size and style of finish. The size, prices, etc., of these instruments can be learned particularly, by sending a stamp to Geo. A. Prince & Co., Buffalo, N. Y., for their illustrated descriptive catalogue. The instruments given as Premiums, will be sent new directly from the factory at Buffalo, ready boxed, and without expense to the recipient, except for freight.

Premium No. 9—Melodeon.

104 Subscribers at $1 each, (or **182** at 80 cents each) will entitle the person getting up the club to one of *Geo. A. Prince & Co's* **$60 Melodeons** (4½ octaves.) See No. 8.

Premium No. 10—Melodeon.

90 Subscribers at $1 each, (or **130** at 80 cents each,) will entitle the person getting up the club to one of *Geo. A. Prince & Co's* **$45 Melodeons** (4 octaves.) See remarks above. In R.—Higher priced Melodeons will be given for larger lists, in the same proportion.

Premium No. 11—New Cyclopedia.

96 Subscribers at $1 each, (or **140** at 80 cents each,) will entitle the person getting up the club to a set of *Appleton's* **New American Cyclopedia,** now in course of publication, consisting of *sixteen large volumes* of 770 pages each. This is a magnificent work, forming a whole library embracing every topic of human knowledge. Twelve volumes are now ready, and the remaining four will be furnished as fast as issued. The entire design of this work was 15 volumes, but it is found that the immense mass of matter will require 16 large volumes. The work is sold at $3 per volume, or $48 for the set. No better premium could any one devote the Winter evenings than in raising a club of subscribers to secure this for himself and family.

Premium No. 12—Best Dictionary.

18 Subscribers at $1 each, (or **40** at 80 cts. each,) will entitle the person getting up the club to a copy of *Webster's Pictorial Unabridged Edition of* **Worcester's Dictionary.** (Price $7.50.) This now stands confessedly the most valuable Standard Dictionary published. It weighs about **10** lbs., is **12** inches long, **10** inches wide, nearly **4** inches thick, and contains **1854 pages** of columns each, giving the spelling and pronunciation, with full explanations, of every word in the English Language, and as a source of general information on all subjects, stands next to the Cyclopedia. The Dictionary can be called for at our Office, or be sent by Express or otherwise, to any part of the country.

Premiums Nos. 13 to 17—Back Volumes.

These premiums (13 to 17,) will enable any one to secure the previous excellent volumes of the *American Agriculturist*, as far back as Volume XVI. We have stereotype plates and can print any number desired of the English Volumes 16, 17, 18, 19, and of the German Volumes 18, 19, and 20. These will be sent in clean, new numbers, each volume by itself, with index complete, and be forwarded *postpaid*. The whole can be taken together, or one or more copies of any particular volume be selected, as desired. They will be presented as in the table above, viz: For **16** Subscribers at $1 each, (or **30** at 80 cents each,) we will present **five volumes.**—For **13** Subscribers at $1 each, or **26** at 80 cents each, **four volumes.**—For **10** Subscribers at $1 each, (or **20** at 80 cents each,) **three volumes.** —For **15** Subscribers at 80 cents each, **two volumes.** —For **10** Subscribers at 80 cents each, **one volume.** —Let every one selecting these premiums be careful to name just *which* back volumes are desired.

Premium No. 18—Paints.

20 Subscribers at 80 cents each, will entitle the person getting up the club to an assortment of *Windsor & Newton's* **Oil Color Paints**—consisting of 12 colors, put up in a neat mahogany case, with brushes, etc. These Paints are imported from London, and are by all considered the best in the world. They are adapted to the finest work, or they will make a neat and appropriate present to any of our young cr readers. They will be sent post-paid any where in the United States within 3000 miles.

Premium No. 19—Paints.

15 Subscribers at 80 cents each, will entitle the person getting up the club to an Assortment of *Osborne & Hodgkinson's* **Water Color Paints,** consisting of 24 colors or shades, put up in a neat case with brushes, cups, etc. These are of American manufacture, and though not so fine as the above, will answer for ordinary practice by children or beginners, and for common sketching. Sent same as No. 18.

Premium No. 20—Corn Sheller.

21 Subscribers at $1 each, (or **40** at 80 cents each,) will entitle the person getting up the club to one of the best **$6½ Hand Corn Shellers.** This is a convenient, useful implement, very frequently called for. We give the best implement we can obtained for this price.

Premium No. 21—Hay Cutter.

24 Subscribers at $1 each, (or **48** at 80 cents each,) will entitle the person getting up the club to one of the best **$8 Straw and Hay Cutters.** This is a useful implement, needed wherever horses and cows are kept.

Premium No. 23—Subsoil Plow.

24 Subscribers at $1 each, (or **48** at 80 cents each,) will entitle the person getting up the club to the best **$8 Subsoil Plow** (two-horse), a very desirable implement.

Premium No. 23—Good Books.

Here is an opportunity to get a good library at little expense. Any person getting up a club of **16** or more names, may choose any desired Books from the list advertised on page 62, *to the amount of 12½ cents for each name sent*, or 80 cents, (or 100 cents for each name sent at $1). The books will be *delivered to the recipient free of all expense for postage.*

Advertisements.

Advertisements to be sure of insertion must be received at latest by the 15th of the preceding month.

TERMS—(invariably cash before insertion):

FOR THE ENGLISH EDITION ONLY.

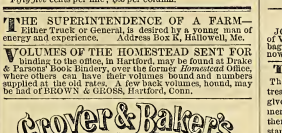
Fifty cents per line of space for each insertion.
One whole column (115 lines), or more, $60 per column.

FOR BOTH ENGLISH AND GERMAN.

Fifty five cents per line; $65 per column.

THE SUPERINTENDENCE OF A FARM—Either Truck or General, is desired by a young man of energy and experience. Address Box K, Hallowell, Me.

VOLUMES OF THE HOMESTEAD SENT FOR binding to the office, in Hartford, may be left at Drake & Parsons' Book Bindery, over the former *Homestead* Office, where others can have their volumes bound and numbers supplied at the old rates. A few back volumes, bound, may be had of BROWN & GROSS, Hartford, Conn.



FOR FAMILY AND MANUFACTURING USE.
495 *BROADWAY, NEW-YORK.*

THE GROVER AND BAKER S. M. CO., now offer, in addition to their splendid stock of Machines making the celebrated GROVER & BAKER STITCH, their superior SHUTTLE, or "LOCK-STITCH" MACHINES, adapted to all varieties of sewing. Much more *Simple, Durable, Noiseless and Perfect* than any "lock-stitch" machines heretofore in use.

FOR SEWING MACHINES.

JONAS BROOKS & BROTHERS' PRIZE MEDAL SPOOL COTTON,

WHITE, BLACK, AND COLORED.

200 or **500** yard spools.

For MACHINES, use BROOK'S PATENT GLACE for upper thread, and BROOK'S SIX CORD BEST TICKET for under thread. Sold by all first class dealers in city and country; also in boxes of 20 dozen each, assorted numbers, by WM. HENRY SMITH, Sole Agent, 36 Vesey-st., New-York.

THE NEW LETTUCE!

TRUE BOSTON CURLED LETTUCE.—I introduce this new variety as surpassing all varieties of the Lettuce family in excellence and elegance. I have little confidence in the rare beauty of its structure and unequalled symmetry of its growth. It is perfectly hardy. Packages containing seed sufficient to supply a family for a season, with directions for cultivation, post-paid, 30 cents; six packets $1.

JAMES J. H. GREGORY, Marblehead, Mass.

SEEDS—SEEDS—SEEDS.

FIELD, GARDEN AND FLOWER SEEDS.
Received from reliable growers in this country and in Europe. Sold at wholesale and retail.
GRIFFING, BROTHER & CO.,
Agricultural and Seed Warehouse,
No. 60 Courtlandt-st., New-York.

CHOICE GARDEN SEEDS BY MAIL.—The subscriber is extensively engaged in raising all kinds of Garden Seeds, which he will furnish in any quantity and of the choicest quality. Under the present law, seeds can be sent by mail at one cent per ounce postage. A new retail catalogue, at greatly reduced prices, is just published, and will be sent to all applicants.
G. R. GARRETSON, Flushing, N. Y.

TREES AND PLANTS.

We are able to offer this season.

Pear Trees

in larger quantities than ever before. They are of fine size good quality, and our own growing.

Our Apple, Cherry, Plum, and other Fruit Trees, are also very handsome and thrifty, and are sold at greatly reduced rates, by the quantity. These, as well as our

Ornamental Trees,

are grown of large size.—Our collection of

Exotic Plants

is finer than ever before. For catalogues, apply to

PARSONS & CO.,
Flushing, L. I.

New-Brunswick Nurseries. New-Jersey.

AND

ANTI-FRICTION
HORSE POWERS.

These Mills and Powers took TEN FIRST PREMIUMS at Western State Fairs last year, and are justly considered superior to all others.

These Mills can be run by any HORSE, WATER, or STEAM POWER, for grinding all kinds of GRAIN, SPICES, COFFEE, PLASTER, BONES, SOAP STONE, &c. They have no equal.

Large Mills are made for milling purposes requiring but ONE HALF THE POWER to do the work of the large flat stone mills.

The HORSE POWERS have many advantages over those of other manufacture.

See *American Agriculturist* for 1861, pages 237 and 288, also page 31, in this volume.

Agents wanted in every county. Rights for sale.

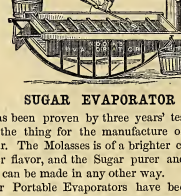
IMPORTANT TO MAPLE SUGAR MANUFACTURERS.
COOK'S



SUGAR EVAPORATOR

Has been proven by three years' test, to be just the thing for the manufacture of Maple Sugar. The Molasses is of a brighter color and richer flavor, and the Sugar purer and whiter than can be made in any other way.

Our Portable Evaporators have been tried upon the Southern plantations, and found to surpass, in speed and economy, the best steam apparatus yet devised. Since then they have been

ADAPTED TO A BRICK ARCH,

by which their speed has been very much increased, so that THEY ARE NOW BEYOND ALL COMPETITION.

Read what Maple men say:

From N. B. Greeley, (brother of Horace,) Clymer, Chatauque Co., N. Y.

"We manufactured one thousand pounds with less than two-thirds of our former expense, and the sugar worth two cents per pound more."

From Rev. J. B. Walker, of Sandusky City.

MESSRS. BLYMYERS, BATES & DAY: "In my trial of it in the manufacture of maple sugar, the Evaporator accomplishes all I hoped.

I had one introduced into our new Christian Colony, which is being settled in Traverse Co., Mich. It was operated by a new hand who had never seen one used. The result was the production of the finest maple molasses and grained maple sugar that I have ever seen."

From M. C. Morgan, Bennington, Vt.

It *saved half the wood and time*, and the sugar and syrup were of a purer quality, altogether, than I had ever made before."

From Levi Hart, Palaskiville, Morrow Co., O.

"The syrup of the first run looked like the white of an egg, or the clear honey that young bees make. It takes less fuel than any other way of boiling I have seen."

From P. M. Henry, Pres. Ag. So., Bennington, Vt.

"NORTH BENNINGTON, Vt., 1860.

"I used one of the copper pans last season, and I am confident I saved one-third of the wood, and boiled away say one-third faster, and made sugar worth 10 to 15 per cent. more than with the same sized pans or kettles, set and used in the ordinary way. (Maple.)

Respectfully yours, P. M. HENRY.

From George Campbell, Westminster, Vt.

"There *is found*, in 'Cook's Portable Sugar Evaporator' a *new and valuable principle* that our old pans do not possess. You can make better sugar, boil faster, and it takes less wood and time to boil the same amount of sap in this pan than in any other I have seen."

We might also refer to Hon. J. H. MILLIKIN, of the Ohio State Board of Agriculture, Hamilton, O.; A. WILLIAMS, Hawley, Mass.; A. B. ARMSTRONG, Dorset, Vt., and hundreds of others, who have used them.

Address BLYMYERS, BATES & DAY, Mansfield, O.; Or, A. B. ARMSTRONG, Dorset, Vt.

TERRITORY FOR SALE!

On account of the remoteness of the territory from our manufactory, we will dispose of the right to Cook's Patent for New-England and New-York.

THE NEW-YORK TRIBUNE.
Large Premiums!
TO OUR FRIENDS.

Hitherto, we have never offered any one a premium for helping to extend the circulation of THE TRIBUNE. We have printed the cheapest newspaper, considering the outlay by which it is produced, that was ever issued in any country selling it for little more than the cost of the white paper; have employed no agents to canvass for subscribers, and have allowed no compensation (beyond a copy of our paper) to any of the thousands of generous friends who have annually taken care that the number of copies of our several issues circulated in their respective neighborhoods should be at least maintained, and if possible increased. We have been sparing even of verbal thanks to these friends, but have none the less realized the fullness of our obligation for their earnest, unselfish, painstaking, persistent efforts.

We propose for the present season only—In view of the hardness of the times, and the fact that we are enabled to buy white paper somewhat cheaper than we have hitherto done, or can hope to do after the close of the War—to make some small acknowledgement—not so much a recompense as a slight testimonial—to those friends who shall see fit to exert themselves to obtain subscriptions (whether original or renewals) to our Weekly and Semi-Weekly editions. We do not know that we could offer anything of similar value more generally acceptable and useful than a Gold Pen of the best quality and finish. We propose, therefore, to forward to each person who, during the two months ensuing, shall send us subscriptions and payments for THE TRIBUNE, as follows:

Weekly Tribune.

For **$12**, Ten Copies Weekly Tribune, and one copy free, *addressed to each subscriber*, and Pens or Pens and Cases to value of..... **$1 00**
Additions can be made at **$2** each.

For **$10**, Ten Copies Weekly Tribune, and one copy free, *to one address*, and Pens or Pens and Cases to value of..... **1 00**
Additions can be made at **$1** each.

For **$20**, Twenty Copies Weekly Tribune, and one copy free, *to one address*, and Pens or Pens and Cases to value of..... **3 00**
Additions can be made at **$1** each.

For **$40**, Forty Copies Weekly Tribune, *to one address*, and Pens or Pens and Cases to value of..... **8 00**
Additions can be made at **$1** each.

For **$50**, Fifty Copies Weekly Tribune, *to one address*, and Pens or Pens and Cases to value of..... **10 00**
Additions can be made at **$1** each.

For **$80**, Eighty Copies Weekly Tribune, *to one address*, and Pens or Pens and Cases to value of..... **18 00**
Additions can be made at **$1** each.

For **$100**, One Hundred Copies Weekly Tribune, *to one address*, and Pens or Pens and Cases to value of..... **25 00**
Additions can be made at **$1** each.

$1 20 each will be required in all cases where the Paper is to be addressed to each subscriber.

Semi-Weekly Tribune.

For **$11 25**, Five Copies Semi-Weekly Tribune, and Pens or Pens and Cases to value of **$2 00**
Additions can be made at **$2 25** each.

For **$20 00**, Ten Copies Semi-Weekly Tribune, and one copy free, *to one address*, and Pens or Pens and Cases to value of **4 00**
Additions can be made at **$2** each.

For **$40 00**, Twenty Copies Semi-Weekly Tribune, *to one address*, and Pens or Pens and Cases to value of..... **10 00**
Additions can be made at **$2** each.

For **$60 00**, Thirty Copies Semi-Weekly Tribune, *to one address*, and Pens or Pens and Cases to value of..... **17 00**
Additions can be made at **$2** each.

For **$100**, Fifty Copies Semi-Weekly Tribune, *to one address*, and Pens or Pens and Cases to value of..... **30 00**
Additions can be made at **$2** each.

$2 25 each will be required in all cases where the Paper is to be addressed to each subscriber.

The Pens will be of the manufacture of A. Morton, whose make we are using, and we believe to be the best made. They will be furnished at the manufacturer's lowest prices. To choose as to the style and quality of Pens or Pens and Cases wanted for premiums, our friends are referred to the manufacturer's price list in another column. See "The Pen is Mightier than the Sword," and be particular and specify the number and quality of the Pens or Pens and Cases preferred.

As these Pens will be selected and sent by A. Morton, No. 25 Maiden-lane, any correspondence in regard to them, after their first reception, must be addressed to him, and not to THE TRIBUNE.

Specimen Copies of The Tribune sent when requested.

When Drafts can be obtained, it is much safer than to remit Bank Bills. The name of the Post-Office and State should in all cases be plainly written.

Payment always in advance.

Address THE TRIBUNE, No. 154 Nassau-st., New-York.

THOROUGH BRED AYRSHIRES, ALDERNEYS and DEVONS at prices to suit the times, for sale by ALFRED M. TREDWELL, Madison, Morris Co., N. J.

VOSBURGH & LUDDEN, (Successors to Warren & Ludden,) Manufacturers of Fine Gold Pens, also Gold and Silver Cases, in all their variety. We would call the attention of the public to our stock of pens and cases, which we feel confident, are superior to any in market, and at such prices that we defy competition. We also call the attention of business men to our new patented Pen-holder, which is composed of several different metals; the same is plated with fourteen carat gold, with diamond points—the points being selected from the best Iridium. The Pen is of mammoth size, and is equal to a fourteen carat gold Pen. It slides on a pencil, and on the upper end we attach a writer. It is the most flexible, cheapest, and consequently the most desirable pen in use. The excellence attained in the production of this Pen has been accomplished by a series of experiments extending over eighteen years, and it must take precedence of all others. P. S.—All orders will be promptly attended to, and on the most reasonable terms. Room No. 4, (up stairs,) No. 169 Broadway, New-York. Manufactory, No. 3 Stanton-st., Brooklyn, L. I.
W. G. VOSBURGH, W. A. LUDDEN.

Box 325, Chicago, Ill.
See December number for description.

TRUSSES.—MARSH & CO.'S Radical Cure Truss, No. 4 Vesey-st., opposite the church. All kinds of Trusses, Supporters, Military Shoulder Braces and Dr. Wadsworth's Uterine Elevator. Elastic stockings, and Mechanical appliances for deformities. (A female attends ladies.)

A Slight Cold, Cough, Hoarseness, or Sore Throat, which might be checked with a simple remedy, if neglected, often terminates seriously. Few are aware of the importance of stopping a Cough or Slight Cold in its first stage; that which in the beginning would yield to a mild remedy, if not attended to, soon attacks the lungs.

Brown's Bronchial Troches were first introduced eleven years ago. It has been proved that they are the best article before the public for Coughs, Colds, Bronchitis, Asthma, Catarrh, the Hacking Cough in Consumption, and numerous affections of the Throat, giving immediate relief.

Public Speakers and Singers, *will find them effectual for clearing and strengthening the voice.*

Sold by all Druggists and Dealers in Medicine, at 25 cents per box.

150,000 BARRELS POUDRETTE.

Send your orders early, and you will be sure to get them filled. Address GRIFFING BROTHER & CO.,
Agricultural and Seed Warehouse,
No. 60 Courtlandt-st., New-York.

PROVIDENCE COMPANY'S CONCENTRATED BONE FERTILIZER.

This is the best Fertilizer, at the price, ever offered to the farmer.
It is composed of pure bone, ground fine, with other materials added of very superior quality.
It powerfully stimulates the plant from the moment the seed germinates, till harvest.
It will not outy fill the farmer's crib, but will enrich the soil, too.
It is packed in good flour barrels, and delivered to vessel or railroad, in New-York City, free of charge to farmer, at the following prices:
For one ton, $67; two, $130; three, $5; four, $5 50; five, $6; six, $9 50; seven and over, $1 50 per barrel.
Two barrels will make an acre of corn in the hill.
Send your orders, inclosing the cash, by mail to

No. 60 Courtlandt-st., New-York.

100,000 BARRELS
OF THE
LODI MANUFACTURING COMPANY'S
POUDRETTE,
FOR SALE BY
JAMES T. FOSTER,
No. 66 Cortlandt-st., New-York.

The large facilities which they enjoy by exclusive contract for all the night soil of the City of New-York, and large capital invested in their extensive works, enable them to manufacture an article which is superior to any other fertilizer in market, taking *cost and yield* into consideration. It will be sold at the usual price of $1 50 per barrel for seven barrels or over, delivered free in New-York City.

Please take notice that the office and sale of this Company's Poudrette is changed from Messrs. Griffing, Brother & Co., No. 69 Cortlandt-st., to No. 66 CORTLANDT-ST.

Other brands of what purports to be Poudrette are in market, put up in barrels to resemble this. Beware of frauds—buy that only which has the brand of the Lodi Manufacturing Co. Any other article is comparatively worthless.

We call the attention to the following experiences of practical farmers, in different sections of the country:

NORTH PEMBROKE, Mass., Oct. 7, 1861.

James R. Dey, Esq., President of the Lodi Manufacturing Co.:

Dear Sir—The early autumnal frosts for several years past have seriously injured our corn crops, and rendered it necessary for farmers in this section to seek some fertilizer to give their crops an early start, in order to bring them to maturity in season to avoid that calamity. Having experimented with Guano, Superphosphate of Lime, etc., with indifferent success, in the Spring of 1860 I purchased four barrels of the Lodi Manufacturing Co.'s Poudrette, which I applied principally to my corn crop, with the most satisfactory results. This was the first Poudrette ever introduced into this vicinity. Last spring I procured from your branch office in Boston about thirty barrels, the most of which I sold to my neighbors, who had witnessed the effect of my last year's trial, which, so far as has been heard from, has given universal satisfaction. To further test the efficacy of your Poudrette, this season I ploughed about two acres of light, sandy soil, which had laid in grass about six years, (the last crop of grass being very light.) This I planted with corn and potatoes, and after the ground had a half barrels of Poudrette, with no other manure, except a handful of ashes to each hill at the first hoeing. From present appearances we shall have a better crop than on a field of like soil where we applied seventy loads of manure to the acre. Its effects on garden vegetables are equally apparent. I am, very respectfully,
HORACE COLLAMORE.

MERRILL, Me., Oct. 11, 1861.

Lodi Manufacturing Co.:

Sir—I bought of your agents, Cross & Newell, two barrels of your Poudrette, and in using the first, I got sick of it and sold the other barrel. But the one that I used I tried the principal part on potatoes. I used about half a pint to the hill, and the yield was equal to those planted on manure at the rate of twenty loads to the acre. My neighbor, who bought the other barrel, says if he had bought five barrels more, he would have got the price of twenty-five.
Yours, &c., V. B. PAUL.

WALDO, Me., Oct. 12, 1861.

To the Lodi Manufacturing Co.:

Gentlemen—Last Spring I bought of Cross and Newell one barrel of your Poudrette as an experiment, but with very little faith in its utility. I put it in six rows of corn in different parts of the field, after manuring with barn-yard manure, in the usual way, at the second time hoeing. Where I put in the Poudrette the corn was twice as large as the rest of the field, and this now is one-third heavier, and has ripened about eight days earlier. I think, if the very thing we want for raising corn in this country, and shall use it more extensively another year.
Yours, &c., WELLINGTON SHOREY.

SAYBNA, Del. Oct. 1, 1861.

Gentlemen—I had heard of the Poudrette you manufactured by the Lodi Manufacturing Co., and thought I would try a small quantity on a lot of land intended for corn, and as it could not get it nearer than Philadelphia, I went and bought of the agent twenty barrels, and applied two barrels to the acre, dropping the corn and a handful of Poudrette in each hill. I left out a part of two rows, and put no Poudrette, to ascertain if there was any value in it, and noticed those two rows during the season; and where the Poudrette was used, the corn was decidedly the best, and I have no hesitancy in saying it is a good manure for corn. I am certain I made from one-third to one-half more by using it.
Yours, respectfully, JOHN G. BLACK.

CHESTER, Pa., Sept. 15, 1861.

To the Lodi Manufacturing Co.:

Gentlemen—I purchased this season of Messrs. Baker & Co., eleven barrels of Poudrette and one bag of Phuine, which I put on my corn. I marked the place where I put the Phuine, which, when started, seemed ahead, but now the corn where the Poudrette was put on is much the best. Last year I used Allen & Needle's new Fertilizer, which did no good at all, as the corn done better without the manure. I think the Poudrette made by your Company the cheapest manure in use.
Yours, &c.,
A. R. PERKINS

The Company's pamphlet, containing directions for its use, with other valuable information and the experience of over one hundred farmers, will be sent free to any one applying for the same. Address,

JAMES T. FOSTER,
Care of Lodi Manufacturing Company,
66 Cortlandt-st., N. Y.

See Here!

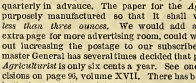
Nearly *Two Thousand* persons have already secured one or more of the good premium articles noted on page 60. But the stock is yet unexhausted, and a thousand more may still each obtain some of the useful implements, books, etc., offered.—Please look over the various topics discussed in this paper. Including the recipes, there are more than *Two Hundred* separate items in this single February number. With such a paper to show, and talk about, it would seem to be not very difficult to fill up a Premium Club already started, or to get up an entirely new one, during this month, and thus obtain cheaply a Labor-Saving and Clothes-Saving Wringer, or a Sewing Machine for the wife; a Barometer, or Hydropult, or some good back Volumes, or a Corn Sheller, or a Straw Cutter, or Sub-Soil Plow, or Chest of Tools, or Good Books, for the husband; or a fine Melodeon for the daughter, or the School, or the Church; a Chest of Tools for the boys, to teach them to be "handy;" or a Great Dictionary, or the Splendid Cyclopedia, or good Books, for the Family or for the Library of the Farmers' Club.—Not a thing is offered that is not really good and *worth* its price, and we take pleasure in presenting these things to those who circulate the *Agriculturist*, and thus benefit our list, and at the same time benefit themselves, and also those who are persuaded to *read*.

Worthy of Special Preservation.

Probably most subscribers preserve all the copies of the *Agriculturist*. Where this is not done regularly, we suggest that the present number will be worthy of special preservation for future reference. The summing up of the previous year's transactions in Breadstuffs given in the Market Review (p. 59), the statistics of the live stock markets, the numbers and prices; the weights and values of different parts of the animals, and modes of selling (p. 58); the fifty four separate recipes or directions for making Corn Bread and Corn Cake—these, and other items of information in the "Basket" and elsewhere which have cost us great labor to prepare and condense, will make this number particulary worthy of being kept. But this is only the twelfth part of a volume, and we hope and intend to make all numbers worth keeping.

The Postage on the Agriculturist is positively only Six Cents a Year.

We hear that several Post Masters are charging 12, 18, 36, and even 72 cents a year on the *Agriculturist*. This is wrong. The law expressly says that a Periodical issued at stated periods, and not weighing over 3 ounces avoirdupois, shall be charged *one cent* per number, and only *half* this sum if paid quarterly in advance. The paper for the *Agriculturist* is purposely manufactured so that it shall weigh a little *less than three ounces*. We would add an occasional extra page for more advertising room, could we do so without increasing the postage to our subscribers. The Postmaster General has several times decided that postage on the *Agriculturist* is only six cents a year. See one of these decisions on page 95, volume XVII. There has been no change in the law or in the weight of the paper since. The paper must be weighed *dry*, and *without the wrapper*. Subscribers will please promptly inform us of any future over charge.



Can at any time be increased, by remitting for each addition, the price paid by the original members—provided the subscriptions all date back to the same starting point. The back numbers will of course be sent to added names.

Bound Volumes—Binding—Covers.

We have complete sets of Vols. 16, 17, 18, 19, and 20, both unbound, and bound separately in neat covers with gilt lettered backs.

PRICES AT THE OFFICE.

Volumes 16, 17, 18, 19, and 20, *unbound*.....$1.00 each.
Volumes 16, 17, 18, 19, and 20, *bound*.....$1.50 each.

PRICES WHEN SENT POST-PAID BY MAIL.
(*They can not go unpaid.*)

Volumes 16, 17, 18, 19, or 20, *unbound*.....$1.12 each.
Volumes 16, 17, 18, 19, or 20, *bound*.....$2.00 each.

BINDING.—Sets of numbers brought to the office will be bound up neatly in our regular style of binding the *Agriculturist* for 50 cents a volume.

PREPAID COVERS.—Covers for binding, neatly made, with title, etc., gilt upon the back, ready for the insertion of the sheets by any bookbinder, can be furnished for Vols. 12, to 20 inclusive, at 25 cents per cover. *Covers can not go by mail.*

Northern Grown Cotton—One Hundred Dollars ($100) in Premiums.

There is at present a good deal of interest in the subject of raising Cotton for Manufacturing Uses. We think it can be grown as far North as 40°, and perhaps further North, with profit. To do our part in stimulating experiments, we make the following offers:

I.—We will pay a Premium of **Thirty Dollars** for the Best ten pounds of Cotton (unginned), grown anywhere *North of Latitude* 40°, during the year 1862. The sample to be exhibited at the Office of the *American Agriculturist*, No. 41 Park-Row, New-York City, during the Autumn of 1862. The time of exhibition and other particulars will be published hereafter.....**$30.00.**

II.—We will pay a Premium of **Twenty Dollars** for the *Second* Best specimen of ten pounds of Cotton, grown and exhibited same as No. 1.....**$20.00.**

III.—We will pay a Premium of **Ten Dollars** for the *Third* Best specimen, (same as No. 1).....**$10.00.**

IV.—We will pay a Premium of **Twenty-five Dollars** for the Best ten pounds of Cotton (unginned), raised *South* of latitude 40°, but North of latitude 38°. To be grown and exhibited as above.....**$25.00.**

V.—We will pay a Premium of **Fifteen Dollars** for the *Second* Best specimen of ten pounds, to be grown and exhibited same as No. 4.....**$15.00.**

Notes.—The samples receiving premiums will be retained on our tables for the inspection of the public. All others will be subject to the direction of the exhibitors, at the close of the Exhibition. The *Agriculturist* having met with unprecedented success, even in these tumultuous times, we gladly set apart the above sums, as our own contribution for the purpose indicated. Probably several Associations will be prompted to make still larger offers. Chinese Sugar Cane was set down for premiums, but we see that abundant offers are already made by the various Societies. We shall therefore turn our attention to other fields of public improvement, of which future announcements will be made.

Seeds not Quite Ready.

As none of our Seeds will go South this Winter, we have not hurried their preparation as much as usual, preferring to wait until we can get all together (including those on the way from Europe,) before commencing to send any out. They will all be started in ample time to reach subscribers before they will need them to plant. The mailing of the parcels will commence the last week in February. Those intending to apply for seeds should do so early in February. (See list and directions on page 35.)

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL-CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, &c., &c., and to HOUSEHOLD LABORS. It has also an interesting and instructive department for CHILDREN and YOUTH.

A full CALENDAR OF OPERATIONS every month. THREE to FOUR HUNDRED, or more, illustrative ENGRAVINGS appear in each volume.

Over TWELVE HUNDRED PLAIN, PRACTICAL, instructive articles and useful items, are given every year.

The Editors and Contributors are all PRACTICAL WORKING MEN.

The teachings of the AGRICULTURIST *are confined to no State or Territory, but are adapted to the wants of all sections of the country—it is, as its name indicates, for the whole* AMERICAN CONTINENT.

A **German edition** is published, of the same size and price as the English, containing all of its reading matter, and its numerous illustrative engravings.

TERMS—INVARIABLY IN ADVANCE.

One copy, one year	$1 00
Six copies, one year	5 00
Ten or more copies one year	**80** cents each.

☞ Add to the above rates: Postage to Canada 6 cents, to England and France, 24 cents; to Germany, 36 cents.

Postage anywhere in the United States and Territories must be paid by the subscriber, and is *only six cents a year*, if paid in advance at the office where received.

All business and other communications should be addressed to the Editor and Proprietor,

ORANGE JUDD, **41** Park-Row, New York City.

FROM THE STEAM PRESSES OF JOHN A. GRAY.

AMERICAN AGRICULTURIST,

FOR THE

Farm, Garden, and Household.

"AGRICULTURE IS THE MOST HEALTHFUL, MOST USEFUL, AND MOST NOBLE EMPLOYMENT OF MAN."—WASHINGTON.

ORANGE JUDD, A.M., EDITOR AND PROPRIETOR. | ESTABLISHED IN 1842. | $1.00 PER ANNUM, IN ADVANCE. SINGLE NUMBER, 10 CENTS.

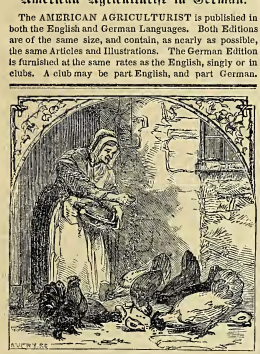
☞ **Contents, Terms, &c., on page 95.**

Entered according to act of Congress in the year 1862, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York. ☞ **N. B.**—Every Journal is invited freely to copy any desirable articles, *if* each article or illustration copied, be duly accredited to the *American Agriculturist.*

American Agriculturist in German.

The AMERICAN AGRICULTURIST is published in both the English and German Languages. Both Editions are of the same size, and contain, as nearly as possible, the same Articles and Illustrations. The German Edition is furnished at the same rates as the English, singly or in clubs. A club may be part English, and part German.



March.

"Not only through the lenient air this change,
Delicious, breathes; the penetrative sun,
His force deep-darting to the dark retreat
Of vegetation, sets the steaming power
At large, to wander o'er the verdant earth,
In various hues; but chiefly thee, gay green!
Thou smiling Nature's universal robe." THOMSON.

There is a feeling of relief, as we reach the first day of Spring, and look back upon Winter as a matter of history. It is very comfortable to remember its frosts and storms, the sheeted earth and frozen streams, as things of the past. Whatever appliances we may use to make the Winter tolerable, it is still a period of endurance, and the farewell with which we dismiss it, is one of the few occasions in which that word sounds pleasantly to the ear. The most enthusiastic lover of sleigh rides and snow banks, skating and ice, is content to put up the sleigh, and fold up the winter furs, and to lay aside the burnished skates. The school boy houses his sled, and lays up the curling stick with a pleasure like that he feels when he takes them out for the winter campaign. The farmer draws his last sled-load of wood over the melting snow with a calm satisfaction, and is hardly displeased if it be left half way home unon the bare field, like Noah's ark on dry land. We all feel that there is something better ahead than the Winter has afforded us. Art has no power to compensate us for what we are deprived of, in the season of storm and snow. We manage to make the dwelling very comfortable by stoves and furnaces, but it is a welcome sound when the last clinker is rattled from the grate, and the furnace door creaks for the last time on its unoiled hinges, and we are glad to have the universal self-acting heater do its appointed work. We hail the lengthening of the days with a rapture that we never feel when the nights grow longer, and the darkness breaks off our unfinished task. And we do this without a thought of economy. It is true that the sun saves in the bills for light and fuel, but how few welcome the Spring with the thought that it will save coal, wood, gas, oil, or tallow candles! Instinctively we hail the opening days of Spring as good and beautiful in themselves. There is no heat like that which the sun gives, and no condition of the atmosphere so genial and enjoyable as that which the sun makes. There is no light so pleasant to the eye as the light of day. Houses are necessary evils, with all their contrivances for heating, lighting, and ventilation. We are glad when we can have twelve hours of sunlight, when we can throw open doors and windows, and drink in sunlight and fresh air, like the birds and plants.

The Winter creates dangers and difficulties which must be met and overcome, to make life at all comfortable. A good part of the Summer is spent in toil to get ready for Winter, and gives birth to an almost endless variety of industry, to meet its necessities. The plow, the loom, and the anvil are all busy, weaving, tilling, forging, to make the season endurable. The discipline under this hard master is invaluable, and it is probably for this reason that so large a portion of the human race have had their lot cast in the temperate zones. Here we find the best types of the race. They have had to struggle for a subsistence, and the conflict with frost and storm, darkness and tempest, has made them strong and heroic. We love to think of the peaceful victories of the ax, and the plow, and of all the wonderful inventions that soften the rigors of Winter, and bring us to the Spring fully prepared for its enjoyment.

These patches of bare earth, we hail them like the faces of old friends coming back to us after long absence. There is a new odor in the atmosphere, though the fields are barren, and not a flower has bloomed. Is it fancy deluding the sense, and bringing up from the yet frozen earth the breath of snow-drops and violets? There is music upon the air, though we see no bird yet perched upon the tree under our window, and the children have not announced the first note of the blue bird, or seen the first robin. It is the trickling song of the eaves, as the snow dissolves from the roof. It is the ripple of the rills as they run by every road side, carrying off the snow banks. It is the softer murmur of the wind from the "sweet south," wooing the buds in every tree top, and whispering to the yet slumbering grasses in the meadow.

We perceive all these things as we look upon the outer world from our loop-hole of retreat. And if we venture forth and hold closer communion with nature, we have still stronger evidence that the reign of Winter is over. We see it in the warmer glow of the sun at his rising and setting. We feel it in the air. Here on the sunny side of the wall, where the snow lay but yesterday, the grass has already started. Lift the covering from the flower border, and you see that the crocuses have already felt the breath of Spring, and are thrusting up their green lance points. There is a busier air in the farm-yard—cocks crowing with fiercer defiance, hens cackling in more obstreperous declaration of new laid eggs, gobblers strutting with redder heads and broader tail feathers, geese hissing at all intruders, and ducks holding a convention on family affairs in every puddle. Here are lambs just dropped, and calves frisking with tails erect, and frothy mouths, guilty of fresh drawn udders. There must be green grass not far ahead for all the new mouths that are opening to crop it.—This attitude of faith and expectation in every living thing, should be cherished by the husbandman. Nature puts honor upon this faith, in every germ that shoots up from the bosom of the earth, in every thing that moves upon its surface. The grass finds abundant aliment, and fills every hungering stomach.

We need, as a class, a much larger faith in our calling. Nature will honor all our drafts upon her bounty, and meet our largest expectations, if we work according to her laws. Here, as in a higher sphere of toil, "he that doubteth is damned." Many a busy toiler upon the farm is kept poor and discouraged by half way measures in husbandry. He has not a large-hearted, generous confidence in the capacities of the soil to reward the capital and labor he expends upon it. There is sunshine enough, and rain enough, and almost food enough, on every acre of soil, to give seventy bushels of corn, if it be skillfully managed. Sometimes it is draining, sometimes deeper plowing, sometimes more tillage, and oftener more manure, that will supply the deficiency, and give full crops. Whatever the want, it should be generously met, that we may reap the full reward of our toils. Half-way plowing, manuring, and tillage, show us skeptics in husbandry. The grand principle, so true in our spiritual relations, is quite as true in our relations to the noble art of agriculture: "Give and it shall be given unto you: good measure, pressed down, and shaken together, and running over." The genial air of the Spring should thaw out the crust of our unbelief, and make us devise liberal things for the soil.

Calendar of Operations for March, 1862.

[A glance over a table like the following will generally call to mind some piece of work that would otherwise be forgotten or neglected. The remarks are more especially adapted to places between 38° to 45°, but will be equally applicable further North and South, by allowing for latitude.]

Farm.

Sunshine and the south wind struggle with the frosts and gales of Winter, and Spring asserts this month her right to rule. The thousand trickling rills, starting under the snow banks and gathering fresh strength and many drops from every softening sod, make hill-side and meadow musical with their liquid voices, giving man notice that water and frost have quit their hold upon the soil, and calling him to his labors. A few degrees south of New-York City, the month of March is really the beginning of Spring but in northern New-York, New-England and the North-West, Winter, and good sleighing, often continue nearly through the month. On warm well drained land work can not commence too soon after the frost and water are fairly out of the soil, but heavy soil is often injured by working while it is wet.

Buildings—Make provision for the increase of the herd and flock, and attend to inside repairs, painting, etc. Delay outside painting until next month. Heavy rains accompanied by wind will injure a coat of fresh paint.

Cattle—Some succulent food is very important to the health of all kinds of stock. Feed a few roots, mangels or rutabagas, daily. Separate cows near calving from the others, giving them wide roomy stalls or boxes. Keep watch to render assistance if necessary. Working oxen must be well fed and not allowed to overwork at first.

Cellars—Clean out decayed vegetables, superfluous sand, or lumber. Whitewash with a simple lime wash, to make them lighter, sweeter, and more healthy. Keep barrels, tubs, etc., where they will not dry or decay.

Clover—May be sowed at any time during the month—best when the ground is frost cracked on a still morning, or else upon new fallen snow, as the seed may then be seen and it can be more easily sowed.

Drains—Should be examined as soon as the frost is out of the ground to see that there are no obstructions. Wet spots in drained land indicate stoppages in drains, which can seldom be repaired before the season is dryer. A perfect system of surface drains is essential at least where underdrains are not laid, and it is more important to have them clear now than at any other season. If possible get in some new drains where needed; it will make the land 3 to 6 weeks earlier.

Farm Accounts—No work done on the farm pays better, than that done in planning and laying out the farm for the future, and in keeping full accounts.

Fences—Re-set posts and walls heaved by the frost; and mend fences before your neighbors turn out their cattle; but do not think of turning your own stock out to grass for two months yet. Happy is he who has a good fence, but happier he who can do away with one.

Grain—Examine that stored in bins. Keep from dampness, mold, insects, and rats and mice.

Grass Lands—Pull out bushes and briars by the roots, remove stones and roll heaved land as soon as the ground will bear the teams. Top dress before rolling with ashes, Chili saltpeter or guano, where desirable.

Hired Men—Lose no time in hiring *good* men for the Summer's work; the opinion prevails that labor will be scarce and wages high, but we doubt it. Don't have a shiftless, lazy, or unprincipled man on the farm at any price. Where several hands are employed, give each his own work, every team its own driver, and let the most skillful be employed in his appropriate department.

Horses—Groom thoroughly; feed carrots (4 qts. a day) to make them shed their coats well and get them in good condition for Spring work. Be particularly careful to guard against colds taken by exposure, when unblanketed, and against galls and sores.

Ice-Houses should be closed up, the ice well covered with straw, ventilation provided in the top of the house. As poor ice is better than none it may not be too late to secure some, if still needed to fill up.

Manure—Manure-making may now progress rapidly. The compost heaps will need working over, manure for the field carted out, and all kinds of litter and scrapings of yards, ditches, sinks, hen-houses, etc., may be composted with muck or earth. Barn-yard leachings, urine and castor pomace quicken inert compost heaps.

Pasture lands may receive the same treatment as grass lands, in kind if not in degree, and on old pastures bone-dust, superphosphate, or leached, or unleached ashes may be applied with good effect.

Plowing is work never to be done in a hurry or on heavy land when the water is not out of it, and never to be slighted. Manure should never be buried deep at this season, unless the land is to be plowed and manured a second time. Deepening the soil by plowing is best effected in the Autumn, but may be done in the Spring in connection with subsequent surface manuring.

Potatoes—Early planting is advisable, and the last of the month is not too early for some localities. It is much pleasanter to sell potatoes for $1.50 per bushel than 50 cents or less, and this our Eastern farmers may do.

Poultry—Give free range in the orchards and fields, feeding grain with corn and cabbages. They will then not eat buds, but find multitudes of insects. Set hens in places where they may be conveniently taken care of and out of the reach of rats.

Seeds—Secure a supply early, and test samples in pots or boxes of earth before sowing or purchasing largely.

Sheep—A successful shepherd is ever watchful, tender, and careful; follow directions given last month.

Swine—Keep a little charcoal and ashes in a corner of the sty, and a handful of flower of sulphur in the swill is a good thing at this season; feed raw roots to breeding sows but not in quantities enough to produce scouring, and give besides a nutritious diet.

Tools, etc.—We scarcely need repeat the injunction, to look well to tools, harnesses and wheel vehicles of all kinds, and have every thing ready for use.

Orchard and Nursery.

Begin work as soon as the ground is open, protecting trees from freezing after they are removed from the ground. Whoever sets out trees should not bring his trees from the nursery before his ground is ready to receive them, and nurserymen always favor their own interests when they aid their customers, even if it seems to be to their immediate disadvantage. Remove crippled or decayed trees in young orchards. On every farm new places can be found for choice fruit trees. A few dollars in trees will be a paying investment in a brief time.

Apple Trees—Scrape off all moss and bark lice, and wash with lye. Leave pruning of large limbs until Summer, but take off suckers and dead wood. Replace poor sorts by grafting with choice varieties. Graft young stocks near the roots (which may be done in the house).

Clions—Cut early in the month, if not already done. Keep covered in sand until wanted for use.

Draining greatly improves land for fruit growing, and in the nursery this is often the only time to drain conveniently. Use rather large tile.

Evergreen Trees—Leave transplanting until May, except perhaps Norway Spruce, and Arbor Vitæ, which can be removed with balls of earth adhering.

Grafting—Begin with stone fruits before the buds swell but after the sap starts; cut grafts and insert as soon as possible. Leave apples and pears until next month.

Insects—The parent of the canker worm ascends the trunks of trees during warm days this month. Many may be destroyed by surrounding the trunks with paper covered with tar mixed with oil enough to keep it soft, and often renewed. Remove scale from the trunks and main limbs, and look for caterpillar eggs near the ends of twigs.

Manures—Apply lime or ashes worked in, in a circle around the trunk as far as the shade falls at mid-day, also top-dress the soil with compost or dung.

Pear Trees—Let there be plenty of choice standards which are as valuable for both fruit and shade around the dwelling. A few dwarfs may occupy a place in the garden. Procure seedling stocks early.

Pruning—Pear and other fruit trees, except apples, may be pruned this month. Prune apple trees with the *knife only*; prune grape vines now, or wait till May.

Stone Fruits—Cherries, Peaches, Plums, etc. Let the homestead be well supplied; good fruit makes any place attractive and adds value.

Seeds of fruit or forest trees kept over Winter, should be planted as soon as the ground is mellow and warm. Sow evergreen seeds and those of mountain ash on the north side of an open fence or otherwise in half shade.

Transplanting—Preserve the roots uninjured as much as possible; pare smoothly the ends of those broken. Reset them as soon as may be after taking up; straighten out the small roots; set at the depth of natural growth in good mold, above soil enriched with compost of leaves or muck, ashes, and a small part stable manure.

Kitchen and Fruit Garden.

Nothing can be done in the open ground until the soil is dry and mellow. Then get out fine manure and spread and spade it in with a spading fork. Now-a-days nobody should use a spade except for digging holes or such like work. There is a good article on the kitchen garden on the 81st and following pages. As soon as the ground is fairly open, work must commence in earnest. The liability to be obliged to replant seeds killed by cold or wet weather, should discourage no one from committing the seeds early to the soil.

Artichokes—Seldom cultivated in this country. Fork in a dressing of manure, being careful not to injure the crowns. Salt and wood ashes are useful. Make new beds.

Asparagus—As soon as danger from frost is past, fork in the manure spread over it last Fall, and give a liberal dressing of salt. Make new beds, using 1 or 2-year old plants which are much better than old roots.

Cabbage and Cauliflower—Sow early in hot-beds, or boxes. Give constant heat and little air at first, afterwards expose much, to harden for transplanting.

Carrots—Sow in open ground, well manured.

Cold Frames—Prepare the plants for removal by continued exposure as the weather grows warmer, but protect from frost. Cabbage, lettuce, celery, etc., may be sowed in the cold frames to advantage at any time after the weather becomes settled.

Cucumbers—Start on bits of sod as described on page 83, and put a few seeds among the earliest lettuce and radish plants in the hot-bed, so that when they are pulled, cucumbers may have the soil and finally overrun the frame.

Draining will benefit any garden where water will stand in post holes 6 hours after heavy rains.

Fruit Trees—Dwarf pears are the only fruit trees we advise to plant in vegetable gardens. These will grow well but are apt to be troubled by insects, hence prune and wash such thoroughly.

Grapes—Uncover vines when the weather is settled, and there is no danger from frost. Fork manure into borders, the earlier the better after they are dry.

Hot-beds for family gardens are best made from the middle to last of the month. Have a good bottom heat and then give abundant air.

Kohl Rabi—Sow with, and treat like cabbage and cauliflower.

Lettuce—Sow early in hot-beds and cold-frames; thin, or pick out to the size one or more apart, according to variety, and stir the soil about them to induce heading.

Manure for the garden should be fine and rich compost. Nothing comes amiss if it be only well rotted. A free use of muck, sods or other vegetable mold is very desirable. Liquid manure, made by using the urine from the cattle stalls or the leachings from the dung heap very much diluted, and judiciously supplied at evening, will astonishingly increase the products of a garden.

Onions—Sow black seed early when the ground is warm, not before. Top onions, or potato onions, for early use may be set in hot-beds, cold-frames, or in the open ground—the earlier the better. Black seed sowed in September affords little bulbs for this purpose much cheaper than top onions which are generally used.

Peas—Sow Daniel O'Rourke and Champion of England when the ground is warm, scalding the seed. See pages 81, 75, and 83.

Peppers—Sow in hot-bed where lettuce is pulled.

Radishes—Sow in hot-beds devoted exclusively to them, and keep the tops as cool as possible.

Rhubarb—See article on page 83.

Sea Kale—Force early with hot manure, covering the crowns with pots or boxes.

Seeds—See hints under Farm operations.

Small Fruits—Currants and Gooseberries, prune and set cuttings, if not done in September. Raspberries, do not lift or tie to stakes before settled weather.

Strawberries—Rake off the beds, fork in fine compost with unleached ashes.

Spinach—Uncover protected beds, loosen the soil, water with liquid manure; sow new beds in warm rich soil.

Sweet Potatoes—Lay whole in the hot-bed, barely covered—for sets for planting.

Turnips—Sow a few as directed for radishes, and in the open ground.

Flower Garden and Lawn.

Wait until the ground is settled warm before exposing tender plants, by removing their Winter protection, and before sowing seed. Many of the perennial flowering plants may be divided and reset, by which an earlier and more perfect bloom will be obtained. Among these are the peony, dicentra, chrysanthemum, sweet william, hollyhock, bee-larkspur, phlox, etc.

Flowering shrubs, especially the early blooming sorts, may also be transplanted as soon as the severity of Winter is past and there is no danger of the ground freezing up again. The disturbance of their rootlets, and the openness of the soil about newly planted trees, or shrubs render them susceptible to injury from hard freezing.

Cuttings of hardy shrubs, etc., such as altheas, spiræas, weigelias, forsythias, lonicbras and the like, may be taken off early in the month before the buds swell. Keep in boxes of earth or sand in the cellar until planting.

Bulb beds which had a coating of manure, leaves, or straw given them for a Winter protection, may be partially or wholly uncovered, toward the latter part of the month; whatever covering they have during March should be light and strawy.

Pruning of roses, and other flowering shrubs, and climbing plants may be done at once. Each plant should be cut back with reference to its flowering habit. By strongly heading back those shrubs which only yield flowers upon the terminal branches or on the old wood, as the magnolia, spiræa, etc., the bloom is nearly destroyed. Roses, especially remontants (or "semi-occasional" bloomers) may be cut back severely, and a finer Autumn bloom is the result.

Box Edgings—May be re-set as soon as the soil is in condition to work. Spread each plant out somewhat fan-shaped, clip off the tops even, and prune the root very close, netting in trench by a line, in sand to secure quick rooting, and pack the earth about the plants with a mallet or pounder.

Grass borders, and turfing generally, may be laid or repaired very early in the season better than later. Let the soil below be mellow, and pack the sods so closely and firmly that there shall be no sinking.

Manure may be purchased at this season rather more favorably, considering every thing, than at any other time. Manure evenly applied upon the land, whether leached or unleached ashes, nitrates, guano, or ammoniacal water, will each and all produce good results, and the present is the best time to manure shrubery and ornamental trees of all kinds for which coarser manures may be used.

Hot-Beds made for starting cuttings, and for sowing seeds are quite indispensable on a large place. Green cuttings, or those of soft wooded plants, need considerable bottom heat, and to be kept cool at top until they strike root. A very little moisture, and give good ventilation, gradually hardening them until they are planted out.

Green and Hot-Houses.

The green-houses and conservatories should now be very attractive, although some of the more showy plants will have gone out of bloom. Everything should be kept neat, with no rubbish, plant trimmings, dead leaves, moss covered pots or boxes, left upon the floor or shelves, or dust suffered to collect upon the leaves. The rooms should be aired frequently when the weather is suitable, avoiding a chilling draft directly upon the plants.

Heat must be regulated according to the object in view. If the house is merely a receptacle of plants designed to be kept from the frost, and which are to bloom in the open borders, then a moderate fire heat, with the thermometer from 40° to 45°, is sufficient. With a collection intended for present flowering, or for inducing a rapid growth to use when the out-door planting season arrives, a temperature of 60° to 75° is needed; and for orchids and other tropical plants, as also for propagating purposes, the houses or rooms may have a temperature of 90° in the sunshine, which must be allowed to fall off naturally at night.

Acacias, heaths, azaleas, and epacris, should be shaded from the direct rays of the sun.

Annuals—Sow in pots as occasion offers, for turning out into the borders in May.

Bedding Plants—Push forward those started last month, pinching in and regulating their shape.

Cacti—Water those showing flower.

Camellias—Those which have done flowering, examine for red spider; wash foliage, syringe, and prune.

Carnations—Make cuttings, set out the old plants for layers; never keep plants more than one Winter.

Frechsias, Chrysanthemums, etc., may be now propagated by cuttings from the new wood. Repot and prune established plants.

Geraniums, pelargoniums, Chinese primroses, cinerarias in or near bloom, keep near the glass, turning frequently.

Insects—Destroy by washing and tobacco fumes.

Pansies are best kept in cold frames, and should be aired and kept back by not admitting the light and heat.

Parlor Plants require even more care than those of the Hot-House. It is an excellent plan to set the pots in larger ones of the same material or of tin, and cover the earth with moss to retain moisture. They will also require frequent turning, especially if growing near the window, to keep them in an erect position. See that the drainage is good and only enough water given to keep the plants in a healthy state; the surface soil may have a dry appearance when there is sufficient moisture at the root. Be sure that there is abundant water always evaporating in the room, or in connection with the fire.

Roses—Established cuttings and plants for early out-door blooming, need re-potting.

Water is required in proportion to the growth of plants. As most plants are now pushing out vigorously, syringe the walls and foliage of plants, and wet the floors to induce a moist atmosphere from evaporation. It will also tend to keep insects in check. The water should not be of a much lower temperature than the atmosphere of the house.

Grapery and Orchard-House.

Cold graperies should be thoroughly whitewashed, mixing flower of sulphur with the wash; the vines may be lifted as the weather moderates, air given on fine days, and the borders watered with liquid manure. Do not tie up to the rafters until all the buds have pushed equally, and keep the house moist when buds are breaking. In more advanced houses, give abundant air, especially where there is bloom; syringe often; thin out superfluous branches.

Orchard House—Give trees in pots and tubs liquid manure in moderate quantities, syringe walls and doors often, and give air freely on mild days. Thin out the fruit. Trees rooted in the ground require manuring and watering quite freely.

Apiary in March.

Prepared by M. Quinby—by request.

The bees will begin to fly pretty freely this month, and in many places to collect pollen. In some sections but little is to be obtained until quite late, yet the weather is often warm enough for extensive breeding in good stocks, if pollen is abundant. The utility of flour as a substitute for pollen is pretty well established. It is difficult, sometimes, to get them to take it, especially when offered after a little is obtained from the flowers, but when given early, and a taste for it acquired, they will use large quantities. If it were of no use whatever after being taken into the hive, I still think it would pay, by keeping the bees employed while they might be getting into mischief by quarreling with, or robbing some of the weaker colonies of the yard, and destroying large numbers. To feed the flour, make a floor several feet square, the size proportioned to the number in stocks. Build it in a warm place within a few rods of the apiary. The unbolted wheat flour is best, but not essential, any kind of flour will probably do; buckwheat, I am informed, has been used extensively. If it has been bolted, mix it with saw-dust, chaff, oats, straw finely cut, or any light substance to prevent its adhering too readily to their bodies. Begin by scattering some on the ground or in the grass near the floor; they will usually find it in a few hours. Keep them busy by feeding every fair day. Perhaps a little caution is necessary not to feed too much. Although I have never been able to find any left in the combs at the end of the season, or to discover any bad effect from giving too much, yet I apprehend their combs might be filled with it to the exclusion of brood. It would probably be safe to give what would average two or three pounds to the hive.

If warm weather should make the bees in the house uneasy, the room should be cooled, and the bees quieted, by putting snow or ice on the floor, until a fine day occurs for putting them out. For removing them, choose a clear warm day. When practicable let each hive occupy its old stand. Set out a dozen, and two hours later, as many more. Put the first as far apart as possible, and fill up the vacant stands as others are afterwards brought out; they will mix together less in the confusion of their first issuing, and a less number be lost by entering the wrong hive on returning. Any stock having lost its queen during Winter, will be likely to show it near evening of the first day they fly out freely, by running about in apparent confusion. A queenless colony now should be united with some feeble stock, unless the queenless one is much superior in numbers, and in other respects will make the best stock; in which case, *that* should receive the bees from the other. The combs and honey of a queenless hive, if all right, may be set away for a new swarm, taking care to smoke with brimstone once or twice to destroy the worms as they hatch out. If the colony that contains the queen is the one removed, there will be some brood in the combs necessary to be taken out before putting away. Be careful and not save for a new swarm any combs containing foul brood. Ascertain the strength of each stock by thorough examination some cool morning. Contract the entrance of the weak ones, till only a single bee can pass at once. Watch for robbing bees on the first warm days—it requires close observation to detect it at first. Ascertain which are destitute of stores, and feed as they require it, taking care not to expose any honey where other bees may get to it.

Seeds for Free Distribution to all Subscribers for 1862 (Vol. 21.).

Every subscriber to the Agriculturist for 1862, is invited to select four or five packets of seeds from the list below.

These seeds are all valuable. Of the 90 kinds offered, many are new varieties, but we include some common useful sorts for convenience of those without seeds to good seeds.

Most of them are annuals (reproducing seed the first season), and in all cases there will be enough to yield a good supply for future use. Our aim is to furnish the germs of future abundance in each locality where these seeds go.

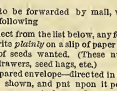
Many of these seeds were grown by ourselves, the past year; the others are obtained from the most reliable seed men and in Europe. The distribution is now going on—will close soon

Mode of Distribution.—The seeds may be called for at the office, or be applied for by mail at any time now The postage is only **1 cent per ounce under 1500 miles; and 2 cents per ounce when over 1500 miles.**

Those sending for seeds to be forwarded by mail, will please *carefully* observe the following

DIRECTIONS—(1). Select from the list below, any four or five parcels desired, and write *plainly* on a slip of paper the *numbers* (only) of the kinds of seeds wanted. (These numbers are used on our seed drawers, seed bags, etc.)

(2) Enclose the slip in a prepared envelope—directed in full to your own address, as here shown, and put upon it postage stamps to the amount of **one cent *for each ounce*** *of seeds to be enclosed*, if to go **under 1500 miles, or two cents** if to go **over 1500 miles.** (Most places West of the Mississippi river are over 1500 miles.) N.B.—The total amount of stamps required can be reckoned from the table of seeds below. Any fraction over even ounces will need a full postage stamp. Use 1-cent stamps according to distance. Forward the above prepared envelopes to this office, and the seeds will be enclosed according to the numbers on the enclosed slip. To save letter postage, let there be *no matter* of business or any other except address and stamps. About 2 ounces will go in a common sized envelope



Field, and Vegetable Garden Seeds.

No.		Weight of package.
185	—Long Bearded Spring Wheat	
3	—Improved King Philip Corn	One or two ounces.
141	—Darling's Early Dent Corn	About one ounce.
186	—Evergreen Sweet Corn	" "
98	—Long Red Mangel Wurtzel	About one ounce.
187	—Conn. Broad Leaf Tobacco	About one-eighth ounce.
188	—Cuculbe Half Long Tobacco	About one-eighth ounce.
189	—Spelt or German Wheat	About one-eighth ounce.
190	—Six Rowed Barley	About one ounce.
8	—Daniel O'Rourke Pea	About one ounce.
9	—Champion of England Pea	About one ounce.
99	—Prince Albert Pea	About one ounce.
12	—Green Kohl Rabi	About one-fourth ounce.
13	—Enfield Market Cabbage	About one-fourth ounce.
15	—Flat Dutch (Winter) Cabbage	About one-fourth ounce.
16	—Imported Scotch Cabbage	About one-fourth ounce.
199	—Red Dutch Cabbage	About one-fourth ounce.
63	—Extra early Round Turnip (Radish)	About one-fourth ounce.
156	—Early Paris Cauliflower	About one-eighth ounce.
74	—Venetian Cabbage Lettuce	About one-fourth ounce.
75	—Imported Brussels Sprouts	About one-eighth ounce.
101	—Improved Long Orange Carrot	About one-half ounce.
148	—Long dark Blood Beet	About one-half ounce.
194	—Extra early Bassano Pea	About one-half ounce.
95	—Hubbard Squash, pure	About one-fourth ounce.
195	—Fejee & Italian Red Tomato	About one-eighth ounce.
154	—Ice-cream Water Melon	About one-eighth ounce.
196	—Skillman's Netted Muskmelon	About one-eighth ounce.
194	—Hollow Crown Parsnip	About one-fourth ounce.
66	—Extra Curled Parsley	About one-fourth ounce.
197	—Early Danvers Onion	About one-fourth ounce.
152	—Fine Large Cheese Pumpkin	About one-fourth ounce.
17	—Red Strap Leaf Turnip	About one-fourth ounce.
71	—Long White French Turnip	About one-half ounce.
195	—Early Short Horn Carrot	About one-fourth ounce.
74	—Solid White Celery	About one-fourth ounce.
102	—Sage	About one-eighth ounce.
156	—Summer Savory	About one-eighth ounce.
198	—Long Prickly Cucumber	About one-eighth ounce.
196	—Green Curled Kale	About one-fourth ounce.
198	—Improved Large Early Frame	About one-fourth ounce.
21	—Winter Cherry	About one-eighth ounce.
197	—Linneus Rhubarb	About one-half ounce.

Flower and Ornamental Seeds.

89	—Cotton Plant (2 kinds, mixed)	One-half ounce.
111	—Castor Oil Bean	One-half ounce.

On an average any **five** *of the following varieties will go under one 1-cent stamp, (or two stamps if* over 1500 miles.)

200	—Fancy Gourds, (mixed varieties) *(An.)*	124	—Wyndvia, *(An)*
201	—Scarlet Chinese Egg Plant, *(An)*	40	—Candytuft, *(An)*
202	—Ashmated Oats, *(An)*	123	—Gilia mvalis, *(An)*
177	—Quaking Grass, *(An)*	182	—Sweet Alyssum, *(An)*
33	—Mignonette, *(An)*	169	—Clarkia pulchella, *(An)*
35	—Mix'd Nasturtium, *(An)*	170	—Mixed Salpiglossis, *(An)*
32	—Calliopsis Pink, *(An)*	168	—Swan River Daisy, *(An)*
32	—Portulacca Mix'd, *(An)*	213	—Xeranthemum Annum *(An)*
34	—Phlox Drummondii, *(An)*	40	—Eschscholtzia Californica, *(An)*
30	—Tassel Flower, *(An)*	126	—Long tubed Cintranthis, *(An)*
37	—Sensitive Zinnia, (Mixed) *(An)*	216	—Acrocliniun Roseum, *(An)*
205	—Double French Marigold, *(An)*	214	—Balloon Vine, *(An)*
183	—Fine Mixed German Asters, *(An)*	27	—Cockscomb, *(An)*
206	—Golden Straw Flower, *(An)*	33	—Cypress Vine, *(An)*
208	—Crimson Globe Amaranth, (everlasting) *(An)*	207	—Ibidanthæ Musgiesii, (everlasting) *(An)*
210	—Convolvulus Tricolor, *(An)*	122	—Mixed Canterbury Bells, *(An)*
172	—Mixed Larkspur, *(An)*	125	—Standing Cypress, *(An)*
167	—Malope Grandiflora, *(An)*	43	—Poppiwes, *(An)*
211	—Fine Mixed Lupins, *(An)*	209	—Dwf Flute Larkspur, *(hp)*
212	—Fine Sweet Peas, *(An)*	171	—Forget-Me-not, *(hhp)*

* *(An.)* hardy annual; *(hAn.)* half hardy annual; *(tn.)* tender annual; *(hhh.)* half hardy biennial; *(tb.)* tender biennial; *(hp.)* hardy perennial; *(hhp.)* half hardy perennial; *(tp.)* tender perennial.

Containing a great variety of Items, including many good Hints and Suggestions which we give here in small type and condensed form, for want of space elsewhere.

The Boys and Girls will please consider the map on page 89 *all their own*. This map was prepared for page 92, but the advertisers demanded that, and though an unusual number of good items, puzzles, etc., were prepared for page 89, we conclude our young friends will prefer the map in these stirring times. The war will soon be over, and now is a good time to fix the geography of the country indelibly in the mind.

Our "War Map" on page 89 gives the outline of a region likely to continue to be the scene of stirring events during the next few weeks. By the crooked route of the Mississippi river it is 1040 miles from Cairo to New-Orleans, though only about 480 miles in a direct line. The reader will readily find Fort Henry, Florence, etc., on the Tennessee river; Dover, or Fort Donelson, Clarksville, Nashville, etc., on the Cumberland; Pensacola and Fort Pickens on the Gulf of Mexico, etc. This map, with those of sundry sections of the Atlantic Coast in previous numbers, and especially the three large and very full maps in November of Kentucky, Tennessee, Missouri, and Eastern Virginia, afford the reader means of finding most of the localities of interest during the present war. Those newer subscribers who have not had the November *Agriculturist*, will probably find it worth while to send 10 cents for a post-paid copy.] Our beautiful map of Eastern North Carolina, given last month, came in admirable time to use in connection with the events of the Burnside expedition, and many have already said it was worth to them the price of the whole volume.

The Seeds Going.—A busy place is our Seed Department now. The mailing commenced at a rapid rate on Feb. 18. But, with all the force we can put on, it will perhaps take to nearly the end of March to forward the hundreds of thousands of parcels already called for. Subscribers need not consider their seed letters miscarried by mail or lost, if they do not get a reply or box so far applied for, before March 30. Those hereafter called for will perhaps reach them later. We regret that some did not read more carefully the simple rules over the seed list, for then we should not find envelopes with no indication of what is wanted; others with the old style P. O. stamps, which require us to put on new stamps at our own expense; others with the numbers written on the *outside*, involving the labor of preparing new envelopes, and transferring the stamps, a thing of no little difficulty; and others so very small as not to hold half the seeds indicated, which involves a new envelope or the piecing out of the old one; and others with too many stamps, a needless expense to the sender.—But hoping for more care hereafter, we will be as patient as possible. We take real pleasure in sending to our subscribers, at so moderate an expense comparatively for each, these parcels of seed which would have cost them 10 to 50 cents or more, where they could have got them at all otherwise.

Pure Chinese Sugar Cane Seed wanted.—From all accounts, it seems that much of the Sorghum or Chinese Sugar Cane seed in the country has been somewhat deteriorated by hybridizing with other plants of the same genus, such as dourrah corn, broom corn, imphee, etc. We have very frequent inquiries as to where pure seed can be obtained, but cannot answer them. Those who have seed to part with, the purity of which they can establish beyond doubt, should advertise the fact: there will be plenty of purchasers. Deeming the matter one of public interest, we several weeks since wrote to a reliable and competent friend in France, to see what could be done there, and if he could find seed positively good, to secure for us all that he could get, at any cost. He is canvassing the country, but has not yet advised us with what success. We expect to hear soon, and if we get the seed, the fact will be announced in the April *Agriculturist*, in ample season for planting.

Sorghum Manufacturers Wanted.—It is as easy to raise an acre of Sorghum, or Chinese Sugar Cane, as an acre of corn. Both require about the same soil and culture. The main difficulty is, that every man disposed to try a small plot does not want to go to the expense and trouble of procuring grinding mills, boilers, etc., nor would it pay on a small scale. We suggest that it would be well for one or more persons in each locality where this crop is likely to be grown, to make arrangements *now* to procure and set up the apparatus, and make contracts with farmers to take the cane and grind it, and boil the syrup, at a stipulated toll. One establishment will answer for from fifteen to thirty persons who only cultivate one to half a dozen acres. It is better that the business should be conducted by a single individual, than for persons to club together, and all have a hand in it. From what we can gather, we estimate that the manufacturer would make a good profit on the clear canes as brought to the mill, and returned sixty gallons of syrup in the one hundred, to the grower; and at this rate it would be better for the latter than to attempt to manufacture on a small scale.

What Tobacco Seed to Sow.—In New-England, sow the "Connecticut Seed Leaf" variety. The same is best for most sections of New-York, Ohio, and Northern Pennsylvania. In other districts it is best to use the seed of that variety for which there is an established market. Tobacco accommodates itself to the locality very much. Havana seed, in Connecticut, soon changes its character, and the broad leaf variety, called "Connecticut Seed Leaf," was brought originally from Maryland, and was modified by culture on the rich meadows of the Connecticut valley. It retains its changed character to a great extent in Ohio.

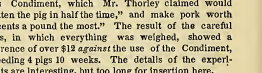
Cotton Grown in Pennsylvania.—Ezra Michener, M. D., Chester Co., Pa., sends for the *Agriculturist Exhibition Tables* a fair sample of unbleached muslin, of which 17 yards were made in that county from cotton grown there by himself. He writes: "In 1858 I obtained seed from a cotton manufacturer, and planted it the same as corn, without manure or extra tillage. It grew well, and the first bolls opened about the middle of ninth month, (Sept.) The cotton was gathered as fast as they opened. Early in tenth month the plants were killed by frost, but many of the maturer plants continued to yield a staple little inferior to the first gathered. ....The fiber was cleaned with a simple home-made machine, consisting of two rollers, one of them turned with a crank, which easily and rapidly pulled off the fiber from the seed....The following season was unfavorable, and no matured cotton was obtained...."

Northern Cotton—Transplanting. The recommendation to sow cotton in a hot-bed and transplant like tobacco or lettuce, must be followed with caution. The cotton plant is *exceedingly* impatient of removal, and must be moved *so as not to know it*. Hence, sow on bits of sod 4 inches square, or in 3 inch pots of good soil, leave in the hot-bed, and transplant to the open ground when danger from frost is past, taking great care not to break the soil or balls of earth turned out of the pots.

To Officers of Agricultural Societies.—We have received several letters, saying that circulars have been sent out to Agricultural Societies, offering 20 copies of a so-called Agricultural paper, without charge, if the prospectus of the paper be printed on the covers of the premium lists; it is asked if the publisher of the *Agriculturist* will do the same. We answer, No; for two reasons: 1st, we trust it is not necessary to give away copies of this journal for the sake of securing the good influence of its being placed on premium lists. 2d. We can not afford it. The *Agriculturist* is wholly a self-supporting institution, and each copy must pay its own way. If we were engaged in other business, and had artificial manures or implements to sell, we might give away hundreds of copies, providing the giving a man a dollar paper put it in our power to induce him to buy artificial manures or implements that would yield us a profit of five to twenty dollars, or more. It would be a good speculation.—However, a good, reliable Agricultural paper is the best premium a Society can give—it is a living, oft-repeated premium, one that stimulates to improvement, and directly benefits a Society. To Premium Committees who think the *Agriculturist* worthy a place in their lists, we will supply the paper as low as we can consistently with our obligations to full paying subscribers. Large numbers of copies are now sent in this way, and have been for years past.

A Bureau of Agriculture.—Congress has at last so far recognized the great Agricultural interest of the country, as to detach it from its long time position of an appendage to the Patent Office, and provided an independent Bureau of Agriculture, having an officer at the head with a salary of $3,000 a year. So far, so good. But if the new Department is to be an improvement upon the old nuisance, it should be placed under the direction of an intelligent, capable, honest man, with special talents and qualifications for the post; one who can take in a broad view of the general agricultural and horticultural interests of the whole country. He must have higher aims than the annual issue of a recipe book got up for Congressmen to send as a tickler to their country constituents. Let us have then, no quack whose chief recommendation is the number of times he has got his name into the papers as a patron of Agricultural shows; nor some self-dubbed "Professor of Scientific Agriculture;" nor an impractical theorist; nor an opinionated "old fogy;" nor one who is not honest enough in providing seeds or plants for distribution to look to the object to be attained, more than to the amount of private per centage that the dealer in old stock will allow him. We will hope for better things now.

"Thorley's Cattle Food."—This so-called food for animals has been as widely puffed and as largely sold in England, as some of the Sarsaparilla syrups (molasses and water) in this country. An agency was established here some time ago and the City and surrounding country literally plastered with flaming showbills. Supposing it to be in the Patent medicine line, we even refused to advertise it. The effects upon animals *claimed* for it, (sickness of hair and plumpness of carcass,) indicated arsenic or antimony. We privately procured some and had it tested at the Yale College Laboratory, but neither of these substances were found. We therefore waited for the practical test, which has now come in authentic form. Dr. J. B. Lawes, of Rothamstead, procured 8 pigs every way alike, divided them into two lots of four each, giving both lots all the barley meal they would eat, but fed one lot the prescribed amount of Thorley's Condiment, which Mr. Thorley claimed would "fatten the pig in half the time," and make pork worth "4 cents a pound the most." The result of the careful trials, in which everything was weighed, showed a difference of over $12 *against* the use of the Condiment, in feeding 4 pigs 10 weeks. The details of the experiments are interesting, but too long for insertion here.



Elder Sap-Spouts.—Some subscriber, whose name and address we have mislaid, recently sent a sketch of his mode of making sap-spouts, or "spiles." He cuts the common elder stalks into convenient lengths, then saws half through on alternate sides, at a and b, and with a chisel splits the piece in two. The pith is pushed out and the ends beveled for entering the auger holes in the trees, as described last month. Such spouts are very rapidly made wherever good elder stalks are to be found.

A Family "Mangle" Wanted.—Now that we can *wring* clothes with a first-rate machine, it is well suggested by a lady reader of the *Agriculturist*, that there is a fortune, and the blessings of all good housewives, in store for the Yankee who shall get up a good, practical family mangle, or ironing machine. She has seen such implements in private families in Europe, that are far better than nothing, but thinks the Yankees can get up a superior one. We heartily second the suggestion.

Onion Culture—New Edition.—The large demand for this valuable Pamphlet (giving the experience of 17 practical Onion Growers,) has rendered a 3d edition necessary—now ready. (Price post-paid, 21 cts.)

Flora Temple.—This famous trotter has been withdrawn from participating in the sports of the course, for the purpose, it is said, of perpetuating her rare qualities in her offspring. It will be hard to keep the "Queen of the trotting Course" away from the scene of so many victories.

Diamonds for Dressing Millstones.—A paragraph on this topic last month closed with a query. Since then a card has come in for our advertising columns indicating that the diamonds were for sale near at hand. Before receiving the advertisement we dropped in to see if the thing were a reality. After looking into the matter a little we begin to think that the thing is not so impracticable after all. Mr. Dickinson's apparatus does seem to do the dressing easily and quickly and that too with a diamond weighing only one-fourth of a caret. The common glaziers' diamonds weigh about one thirtieth of a caret. We should judge the subject worthy the investigation of millers. Mr. D. has left with us one of the diamonds and his new guide, which we shall hand over to a friend, who is a miller, to test.

Starting Delaware Cuttings by Grafting.—Chas. B. Ott, of Bucks Co., Pa., grafted Delaware upon the common frost grape last April, in the following manner: The wild vine was put down as a layer, split through with a knife along the whole length, at intervals of one foot each, and the Delaware cions of two eyes each were shaved down and set in the slits, and the earth filled in around them to the upper eye. About three fourths of them lived, and some made a growth of 15 feet. The wild vine was about one inch in diameter, and the top end was left out of ground to keep it alive

Liquid Medicine Dangerous for Horses.—It is difficult to induce a horse to take fluid medicine, and he is very likely to get it into his lungs and thus produce spasmodic coughing and sometimes, permanent disease, or "broken wind." According to experiments instituted in Hanover (Germany), horses have even been killed in this way. Use medicines in the form of powders, agreeable drinks, or mashes, pills, etc.

Galls on Horses Cured.—E. R. Churchill, Hillsboro' Co., N. H., writes to the *Agriculturist:* "Is it generally known that arnica flowers digested in spirit cures galls on horses very quickly, applied several times a day? It cured a very obstinate case on my own horse last Summer." (The dried flowers are sold at drug stores.)

Bloody Milk.—L. N. P., Ottawa City, Iowa. Garget is probably the cause. Feed a teaspoonful of saltpetre twice daily, and if the bag is caked and sore, rub it with equal parts of arnica tincture and warm water which will take the soreness out, and then rub and *knead* it.

Soiling Stock.—"Subscriber" at Jennerville, Chester Co., Pa., wishes to see in the *Agriculturist* the Dr. and Cr. side of some well conducted soiling experiments, extending through a considerable period. He wishes to know how it affects the health of stock, about the gain in the manure heap, and whether it will pay. There are readers of the *Agriculturist* who are experienced in this—will they respond with the particulars?

The Monster Hog.—We published in the February *Agriculturist* the statement given us by the butchers of the weight, etc., of an immense hog. From the gentleman upon whose farm it was fattened—Mr. Frank Lathrop, of Morris Co., N. J.— we learn that when 2 yrs. 8 mos. old, five months before he was killed, he weighed 1,035 lbs.; that he was imported by David Leavitt, jr., Esq., of Great Barrington, Mass., with the following pedigree: "Bred by Earl of Sefton, Croxteth Hall, Lancashire, England. Pigged Dec. 1, 1858, got by Young Tinker out of Maria; Young Tinker by old Tinker; he by Bruiser; he by Burster, and he by the Berkshire Boar, who weighed 1,175 lbs., when 2 years and 3 months old, and was supposed to be the weightiest pig of his age England has produced. Maria is out of Sal; Sal, by Mot; Mot, a lineal descendant of the Suffolk Punchster, the greatest pig of his age." (Signed), WM. LITTLE, JR.

Farm Steward of the Earl of Sefton.

His weight was stated by Lilly & Brower, who butchered him, to be 1,393 lbs. alive, and 1,053 dressed.

The French Cure for Sheep Rot.—We do not remember to have mentioned that in France during the past year a medicine has come into pretty extensive sale for the rot, a disease which prevails much more generally in Europe than in this country. So great were the claims for this remedy, that the Royal Agricultural Society of England deemed it worth while to appropriate £12 ($60), for the expense of a trial of it in England. Prof. Simonds was entrusted with the experiments, and after a faithful trial during last Summer, he reports that no good results were apparent. It is therefore to be classed with the thousand and one humbug nostrums, cures for consumption, etc., that get notoriety by advertising, deceptive certificates, etc.

Sheep Wanted at the West.—In a letter of Feb. 5th, from F. W. Windship, of Princeton, Bureau Co., Ill., he remarks incidentally: "We want five to ten thousand sheep in this County immediately. Where can we get them, and at what price? If any one can tell, let him address the Secretary of our County Agricultural Society, or myself." (Mr. W. is County Surveyor.)—Similar inquiries come from other points at the West, as well as from some localities in the East. We do not know how the want will be supplied. Farmers are becoming more alive to the profitableness of sheep raising, and probably very few would now be willing to part with their flocks at prices they would be likely to be offered for them. We suggest in this connection, the importance of taking good care of the breeding ewes at this season. Keep them in good heart, not too fat, and let the greatest care be exercised to save and raise all the lambs dropped this Spring.

Sheep—Relative value of Breeds in England.—In the prize sheet for the next Show of the Royal Agricultural Society, prizes of $100 (£20) are offered for the best shearling ram, for the best ram of any age, and for the best pen of five shearling ewes. These are for Leicesters, and Southdowns. Only $75 (£15) are offered for the same classes of Lincolns, Cotswolds, and Kentish or Romney Marsh breeds. Quite a little breeze is being raised by the graziers of the last named three breeds, for, as says one of the number, "this course of the Society is to inform foreigners who come to the Show to buy sheep, that the Cotswold, Lincoln and Kentish are only *second* class sheep, whereas, we (the graziers) think them the most *useful* and profitable class of sheep in the Kingdom ..." A strong appeal is made to the breeders to vote out of office the members of the Council who have made the distinction.

How to Prove the Vitality of Eggs.—De Berri, Rye, N. Y., writes to the *American Agriculturist:* It is emphatically "Love's labor lost" to set her on eggs lacking vitality. For some years I have generally been successful in "counting my chickens before they were hatched." About the 2nd week in March I select *fresh* eggs of a *medium* size, and set as many hens as possible at the same time. After three days examine the eggs at night with a light, those having the embryo chick will appear dark, while those lacking vitality will look clear as ever, remove them as they will not hatch, but are still fit for family use; transfer the good eggs from one nest to another to make up deficiencies, and give the robbed hens fresh eggs.

Yellow Butter in Winter.—R. Downs, New-Haven Co., Conn., puts the cream into the churn, stirs it for a few minutes, and then adds the juice of a good sized yellow carrot. The carrot is grated or scraped fine and mixed with a pint of new milk, and left to soak for a short time, then strained through a very fine sieve or cloth and the liquid added to the cream in the churn. The butter will be as yellow as if made in Summer, with no carrot taste.

"Milk for Babes."—D. J. F., of Troy, writes to the *Agriculturist* dissenting from a view expressed by a writer in this journal, and giving his own practice. He says, "I have had 15 years experience in feeding the unmixed milk from a single cow to infants, sometimes to as many as 7 at once, and have never found a *furrow cow's* milk that a child would thrive on. There are but few new milch cows whose milk is good for infants. When I commence leaving milk for a young child, I always inquire after its health for a week at least, if the milk makes it sick, I change to another cow, and continue to do so until I find milk that is good for the child, then I do not change till the child is weaned, if the cow remains well. Not one milkman in ten is honest in carrying one cow's milk. They find it very convenient to supply the baby's milk out of a 60 quart can.

Concentrated Milk.—Cynthia M. Green, Broome Co., N. Y. No patented process is secret—the Government grants exclusive rights for a term of years, in consideration of the full disclosure, or making *patent*, of the process or method. This milk is concentrated by an expensive process, which is, we believe, patented. The milk is purified, and very rapidly boiled down by means of steam heat and an air-pump at a temperature considerably below that of boiling water, (about 160°,) until 5 gallons are reduced to 1, in which condition it is marketed, and when used it is reduced by the addition of five times as much water and a little salt, which it seems to need, in order to restore the flavor of *fresh* milk.

Lime on a "Truck" Patch.—M. B., of Clinton Co., Pa., asks if it will do to put fresh lime on a "truck" patch. If the soil is rather heavy and has been long receiving its annual supply of manure, or contains much vegetable matter, lime will probably be an excellent application. Apply about a peck to the square rod, sowing on the surface, and working it in. Lime is said to improve a light land. By no means mix it with manure, for its action will set ammonia free.

Salt as Manure.—G. B. Smith, Albany Co., N. Y. Salt is an excellent ingredient in composts, added at the rate of about a peck to the load. It is a good dressing for grass, grain land, and ground where roots are to be grown, and in fact it is seldom without some benefit; yet it is impossible to tell how much or how little will produce the best effect. Sometimes two or three bushels to the acre seems to produce the best results, and sometimes but little effect will be seen from a dozen. You will find an answer to the question about gas lime in the January *Agriculturist*, page 7.

Manure under Shed.—L. Labo, of Pennsylvania, and others. Manure mixed largely with straw and thrown together under cover, without further care, will be in danger of drying out and fire fanging. It should be occasionally forked over, and if not wet enough to continue rotting, water should be thrown on to keep the entire heap always moist. A free addition of muck, or black earth, or sods, or even of common soil, will help to absorb the escaping gasses, and increase the value of the heap materially, unless there be as much straw as can be decomposed by the intermixed droppings of animals. Muck, or black earth, or sods, when composted (mixed) with decaying manure, increase the value of the heap not only by acting as absorbents, but they also add much fertilizing material by the decomposition of their own organic elements.

Hen Manure.—Rygate, Vt. You did not calculate for the strength of the compost made by "drying" hen manure with unleached ashes. Never make such a mixture; ammonia is set free and lost. In this case it was disengaged in the soil and in contact with the seed, and of course killed it. Compost hen manure with soil or muck, throwing it into a heap and working it over two or three times, adding more soil each time, until it is about ⅓ manure, ⅔ soil or muck, and put of this but a handful to the hill of corn. The grass you sent was a variety of *Panicum dichotomum*, one of the "Panic" grasses.

Granite Manure.—"John." Yes, there is such a thing; but it will never drive barn-manure out of use. The *fine* chips or dust of granite quarries, and of the stone-cutters, when strewn over grass-land often produces a marked effect. Granite is composed of felspar, mica, and quartz; and felspar contains about 14 per cent of *potash*. Hence the fertilizing power of the granite.

Muck Swamps which can not be Drained.—M. D. Loper, Long Island. In the Winter cut off all the brush, and in a dry time dig out a place in the lowest part, as deep as you can, for a constant pond, and dig ditches running into it. In this way you will undoubtedly get a good part of your swamp dry enough to dig muck in, even in Winter. If there is a clay bottom to the swamp, and gravel or sand beneath, a boring or well through the clay will tap such a sink, and give drainage.

Grass Land—When to Manure.—Hampden, of Holyoke, Mass., communicates to the *Agriculturist* his experience in manuring grass lands, which we have only room for in a very condensed form: Three years ago, he top-dressed part of a meadow in August; 3 weeks, dry and hot, without rain, followed; he thought all the manure lost. After a few rains, the manured part showed finely and the next Summer the crop of hay was double. The next year, top-dressed a meadow the last of November; saw very little benefit the next season, and this little, perhaps, due to the action of the manure as a mulch or "blanket" rather than as a fertilizer. Last year, manured part of meadow lot in August, the rest in September. The appearances indicate one third larger crop from the August application.

Wire Fence on a Stone Wall.—J. C. Boorse, Montgomery Co., Pa. The manufactured wire netting fence answers a good purpose, fastened to posts set in the ground or in the center of a low stone wall. It can be purchased at most agricultural stores for $1 to $2 per rod, according to the hight, the size of the wire, and the fineness or coarseness of the meshes.

How Much Fall in Drains?—T. Hooper, Kansas. Be sure only that there is a fall. If you are *sure* that a tile drain *falls* 1 inch in 100 feet, and that uniformly, it will do, but it is easier to be sure of 1 foot fall in 100 feet, and 3 to 5 feet are preferable. Stone drains, etc., need a greater fall than tiles, but drains with little fall must be very carefully laid so as not to get out of place or fill up with sand and silt.

Cisterns.—J. M. H., Mt. Vernon, N. Y. You may locate the cistern at almost any distance from the pump by having a tight connecting pipe. The force required depends mainly upon the hight of the pump above the water, though the longer pipe involves more friction from the water. The expense of blasting will probably greatly exceed that of a connecting pipe—you can judge. Roman cement is an English article, so called from its resemblance to the cement found in the old Roman structures of England. Probably none in the world surpasses the Rosendale and Kingston cements. The Croton Acqueduct was laid in these. We can not say which is the best pump.

A Good Cellar.—A. M. Ward, Hartford Co., Conn., thus expresses to the *Agriculturist* his appreciation of a good cellar. "Although living in a hired house, four years ago I had the cellar bottom cemented at my own expense. The walls were rough, destroyed costly brushes in whitewashing, and let in damp, sometimes water, and more especially *rats*, so I kept a tub of mortar on hand in the cellar, with which occasionally of an evening I smoothed off the walls; and then whitewashed. Now it is a pleasant room, with constantly increasing *conveniences*, and is the envy of my *wealthy* neighbors who have nothing in comparison."

Sulphur to Prevent Potato Rot.—It is announced in Austria that carefully conducted experiments prove that sulphur put in the drills with potatoes when planted, has prevented the rot to some extent, and besides, improved the flavor.

Weeds a Remedy for Potato Rot.—A Delaware Farmer says he plants his potatoes as soon as the frost will permit, in Spring, tends them well until they bloom, but never disturbs them after that. Where the crab grass and other weeds cover the ground most effectually there are the fewest rotten potatoes, or rather no rotten ones. The yield is not always as good, but he finds his gain in this practice. He has always found the most rot on naked, dry spots, exposed to the sun. [Weeds or rot—the choice is a hard one.—ED.]

Potatoes—How an Extra crop was Raised.—Turnips.—J. B. F., of Hunterdon Co., N. J., writes to the *Agriculturist* that he had an extra crop of potatoes last year, thus: "Manure was plowed under; the ground then harrowed and struck out with furrows 2½ feet apart. The potatoes were cut 3 eyes to the piece, and the pieces placed 1 foot apart in the drill; ashes were sprinkled on and then a covering of 4 inches of soil. When well up, the plow was run close to the row to throw the dirt away, and then it was thrown back again by running the plow the other way. This loosened the soil and admitted air and warmth. A week after, the cultivator was run between the rows. Just before blossoming the double plowing was repeated. The planting was about April 15; the varieties, Mercers and Buckeyes, which mature before the rot takes place. At the last hoeing turnips were sown between the rows. I have also raised good crops of turnips sown among corn at the last hoeing—the flat and red top varieties grown thus often reaching 4 lbs. weight, and these stored in the cellar with a little dirt over them keep well for cattle until Spring." [Like almost all records of experience sent to us, the above is defective in one or more items; nothing is said of the kind of soil, nor of the kind or quality or amount of manure applied. All such particulars are essential to render one man's experience fully useful to another.—ED.]

Planting Potatoes.—Experiments by S. S. Gregory, Cuyahoga Co., O., reported to the *Agriculturist* indicate that when the seed is cut it will pay well to plant all the pieces flesh-side down. In his experiments a difference of nearly one fifth was obtained.

Keeping Celery in Winter.—J. M., of Lancaster Co., Pa., communicates the following experiment to the *American Agriculturist*: I carefully lifted my celery with as much earth as would adhere to the roots, and set the plants close together in the milk trough in my spring-house, and at once put in and have maintained about 6 inches water in the trough. The celery shows as much vigor of growth now (Jan. 15,) as before transplanting, being much larger now, than when it was dug up, bleached nicely, and the new growth is very fine and crisp, and of course is very conveniently obtained for use. The spring house is built of stone and arched over with brick [and is doubtless dark.]

Heading Cauliflower in the Cellar.—"A Constant Reader," Albany, N. Y., writes to the *Agriculturist* that on the approach of the present Winter he found some thirty cauliflowers that had not matured. These he transplanted into soil in the cellar, putting them near together, with earth around the roots. They were watered occasionally, and every plant matured, producing as fine and large heads as he ever saw. [Not unusual.]

Prolific Pumpkin Vine.—H. A. Terry, of Pottawatomie Co., Iowa, says he raised 42 cheese pumpkins upon a single vine from seed distributed last year by the *Agriculturist*. They averaged 18 lbs. each, making 756 lbs. from the single vine. The main vine and laterals measured 376 feet in length. We call that more than "some pumpkins." The soil must have been very rich naturally, if not artificially.

Transplanting and Pinching Tomatoes.—"Gardener," Lewiston, Me.—Do not shorten the tap root of tomatoes, but pinch back early plants when one foot high, just nipping off the top shoot. Cover early plants during cool nights with flower pots to force them.

Hemlock Hedge.—"O. S." The best way is to get your bushes from a nursery—they will be better plants, and be more likely to live. But if not convenient to do that, then try this method: Having prepared the ground well all along the line of the proposed hedge, when the hemlocks begin to show little green tufts of new leaves on the tips of the boughs, go to the fields, (not to the dark woods,) taking along a sharp spade and some matting to cover the roots. Select small, bushy plants, not more than two feet high, cut a circle around each tree, eighteen inches or more from the stem, and lift the plant, soil and all, into the wagon, covering the exposed roots at once. When the wagon is full, lose no time in getting home and setting out the trees. Mulch them well, and the most, if not all of them will live and prosper.

Evergreens for Cemetery Lots.—G. R. N., Tolland Co., Conn. You will find nothing to answer your purpose better than Arbor vitæ. It will bear trimming to almost any degree or form. Box, though hardy, needs to be protected, or the leaves will turn yellow, and parts of the shrub will become naked or dead.

Peach Trees Laid Down in Winter.—E. R. C., asks: "Can peach trees in the open ground be so dwarfed as to be laid down and covered in Winter?" It may be done, we suppose. The best way is probably to form five straight branches taken as near the ground as possible, and keep them closely pruned and tied down to stakes, so that the outer ends will rise but two or three feet above the ground according to the length. Mr. Camp, of Pennsylvania, has 30 trees laid down this Winter; we have asked for his results after the next fruiting.

Sowing Apple Seeds.—J. H. C., Toledo, directs, in a communication to the *American Agriculturist*, to use seeds washed from unfermented cider pomace. Good seed is bright and plump. Sow in Spring or Fall, half an inch to an inch apart in rows an inch deep, and three and a half feet apart, in good warm land. If sown in Spring they should be mixed with sand and exposed on boards or in boxes to freezing. Keep the land clear of weeds and "cultivate" three or four times in a season. About one third of the plants will be ready to graft at one year old if they do well, and the balance at two years old.

To Propagate the Mulberry.—W. M. S. The Morus multicaulis, and other varieties of the mulberry are propagated by layers and cuttings of single eyes or buds. They root readily in a moderate hot-bed.

Fruit Trees by the Roadsides.—Zechokke somewhere puts words like these, in the mouth of an old mechanic, addressing his son who is on the point of leaving home, in search of work as a journeyman: "If you come into a country where fruit trees are planted along the highways, there *rest*, my son. You are in a country where honest and sensible people live."

Pears—Varieties on a Tree, etc.—Edwin Bloeser, Middletown, Conn. There are no objections to grafting several sorts upon one tree, except that a tree thus bearing several kinds rarely or never exhibits beauty of form. It grows one-sided or otherwise out of shape unless great care is taken to graft one kind on the lower limbs and another in the top—always having in view the size of the pears, the habit of growth, and the tendency of the fruit to fall. Mixing varieties may also make confusion in gathering the fruit.

Good Early Pears.—"J. K."—Madeleine, ripens early in August; Bloodgood, in August; Osband's Summer, do; Dearborn's Seedling, do; Doyenne d'Ete, do; Rostiezer, early September; Tyson, September.

Barren Lemon Trees.—Mrs. Allen, Chautauqua Co., N. Y. Try the effect of getting a few cions or buds of a bearing tree, from some one growing them in a green-house, and bud or graft the barren tree. Budding in June will probably be preferable.

The Austin Strawberry.—An Indiana subscriber sends an advertisement of this berry clipped from the Country Gentleman, and asks if the claims put forth are reliable. They are rather strong. The Austin Strawberry is large, and pretty productive, but not of the best flavor we like. Its greatest merit is that it fruits later than most other varieties, and therefore prolongs the season of this delicious crop. It answers very well, therefore, as one of an assortment in the garden.

Strawberries, Beans.—R. F. C., Mich. The Black Prince strawberry does only tolerably in this country; other varieties surpass it as bearers. The beans taken from the crop of a wild goose are the prairie bean *Phaseolus diversifolius*, common in Canada and the Northwest.

The Green Rose.—"D. S." Not of French origin, as you suppose. Monsieur deserves the credit of originating most of our best roses, but he must not bear off *this* glory. A florist in Baltimore, (his name we do not recall,) first introduced it to the world, about eighteen years ago. An enterprising Philadelphia gardener soon sent it over to England and France, where it produced quite a sensation. The price, at first, was $2 50 a plant. Now, it is as cheap as other good roses. But we advise no one to buy it for its beauty. The flower is only semi-double, and the petals of a dirty pale-green. It is interesting only as a curiosity.

Ten Fine June Roses.—"Alice." You will find the following excellent, though they do not by any means include *all* the first-rate Summer roses: *Aurette*, blackish purple, medium size, globular and double. *Cericette*, bright red, double. *George 4th*, large, purplish crimson, double, but loose, very fine. *Harrison's Yellow*, not fully double, but early and pretty. *Persian Yellow*, fine, golden yellow, double. *Old Cabbage*, needs no description or praise. *Luxembourgh Moss*, bright red and mossy. *Madonna Hardy*, white, nearly double. *Venus*, white, with a delicate pink tinge, double. *La Tourtenelle*, the "dove-colored" rose.

Skeletonizing Plants.—The simplest method is to select firm, perfect leaves of any kind, such as camellia, apple, pear, magnolia, ivy, jessamine; steep the firmer varieties in hot water a few minutes, (this is not necessary with others) and then lay them in cold rain water, and keep them covered by it, for two or three weeks or even more, not changing the water. After this take them out one at a time, and laying them on a plate with a little water, by means of a camels' hair pencil remove the softened pulpy part of the leaf, when nothing but the fibers will be left. These should be perfectly freed from pulp even if another week's soaking be required. Finally, bleach by laying the leaves in a liquid made by putting one tablespoonful of chloride of lime in a quart bottle of water, shake it well, and after it has stood some hours pour off the clear liquid for use.

Non Flowering Wistaria.—Sarah Eldridge, Litchfield Co., Conn. If your Wistaria Sinensis is in an exposed situation, or where the sun starts the buds too early in Spring, lay it down in the Fall, and put it up late in Spring. Dig in a compost about the roots, and if the vine is old and feeble, cut back and train a new shoot.

A Curious Hanging Basket.—Miss E. Slocum, of Fayette Co., Pa., sends the following description to the *American Agriculturist*. Procure a large sized turnip, and scrape out the underside, leaving a pretty thick wall all around; fill the cavity with earth, and plant in it some climbing vine—cypress vine, or morning glory. Suspend the turnip with cords, and in a little time the vines will twine around the strings, and the turnip-sprouting from below, will put forth leaves and stems that will turn upward, and curl gracefully around the base.

Sewing Machines.—Mrs. O. G. N., Dane Co., Wis., inquires about the truth of the statement that in many families sewing machines are laid aside as soon as the novelty wears off, and the needle resorted to. Should we open our columns to testimony of the constant and increasing use of these machines in families where they have been only used, there would be room for nothing else. In our own family we have had them in use for four years and prize them now more than ever. If a woman has no tact or accuracy, or ability to understand simple mechanical contrivances and effects, and is withal disinclined to work of any kind, she will probably neglect her sewing machine after the novelty is worn off.

Milk for Bees.—In some of the Germany journals we see it stated that German Bee-keepers have found sweet fresh milk the best artificial food for bees. This is a new idea to us—not very plausible—and we leave experienced apiarians to condemn or approve.—ED.

Tunneling for a Water Course.—John R. Thompson, Pendleton Co., Ky., asks the cost of making a small tunnel through a limestone rock, 200 yards. He has a stream, with a fifty-foot fall in that case, available to run a mill above the banks of the Licking River. It is to be noted that no man has a right to tap a stream which flows through other men's lands and not return the water to the same stream again. The tunneling will cost under the most favorable circumstances scarcely less than $3 a foot and may cost $10. If the rock be soft and easily worked with the pick and bar, the expense will be least; he may have to use powder for every foot he advances. The tunnel ought to be commenced at each end in order to have good air; a hole 2½ or 3 feet wide, by 5 feet high would be as small as a man could work well. Picks, shovels, sledges, sets of drill borers, iron wedges, crow-bars, and barrows are the

tools needed. The tunnel should be nearly level, to avoid the water wearing, and to have as much fall as possible at the mill. Should the rock be full of cracks and fissures, or should loose ground be encountered it would be necessary to support the sides and top with timber and planks, and the same causes might make it necessary to lay the water course in cement.

Dynamometers.—P. H. Lucas, Crawford Co., Pa. This implement is not usually kept at agricultural implement stores, but is made to order when wanted. The common form was that of a C-shaped spring which the draft opens, and to which a dial and index are attached. The scale was graduated by suspending a platform to the dynamometer and loading it with known weights. Recently elliptic springs have been employed, and are preferred, we believe.

Barometers.—John P. Kast. Hang your Kendall's Aneroid in any convenient room. It will indicate the same in-doors or out, warm or cold, a change of 30 or 40ª of temperature will make scarcely any perceptable difference with it, except for the most scientific observation. Bear in mind that the barometer does not indicate changes of temperature, but gives accurately the *weight* of the air, and from this and from other things, if we know enough, we predict changes.

Best Soil for Plants in Pots.—E. L. Bartholomew, Westfield. We can hardly give a set of arbitrary rules. The best growers make up a general mass and use it for nearly all kinds of plants (excepting heath's and orchids), adding more sand for small rooted plants such as azaleas, lechenaulias, cuneas, etc., and less for the strong-rooted, such as acacias, oleanders, etc. The basis of a general soil is grass sods from old pastures in good condition. These are gathered and piled up with one fourth their bulk of manure—more or less according to their richness—and left a few weeks until they decay so as to crumble easily in the hand. Chopping finely with a spade hastens the decomposition. If leaf-mold (that is black soil of decayed leaves) or peat be at hand they can be mixed with the decayed sods freely. If the sod soil was clayey or compact considerable fine sand should be added to make the whole light and friable. Such a preparation may be made up in large quantity and be kept on hand, always ready for use in pots, and also for covering small seeds sown in drills in the open ground.

Use Earthen Pots for Plants.—Very few yet appreciate the convenience of a few earthen pots of different sizes for starting early plants. They cost but little, and with moderate care will last for years. A few will suffice for the ordinary garden of the farm or village plot. Filled with soil and sown in March with seeds of cabbage, tomatoes, cauliflower, peppers, cucumbers, lettuce, etc., and with various flower seeds if desired, they can be left out on the South or East side of a building except when the air is below the freezing point, in which case they can be temporarily carried into a cellar or warm room. By the time the ground is ready for seed, the pots will afford a supply of good sized plants to set out, and from two to four weeks, or more, will be gained. If the seed be sown in very small pots, or the plants be transplanted into these, a ball of earth can be turned out into the open ground, and the plants receive no check.

The Best Pots for Plants are those made of clear clay. Much sand in the clay glazes them. Small stones or pebbles will crack out on wetting. It is more important to have the inside smooth, than the outside, as the fine root fibers will not attach themselves, and thus prevent the easy removal of the ball of earth in a mass. For a similar reason the bottom should be considerably narrower than the top, and the sides slope uniformly. With pots thus made one can, after a little practice, take out and examine the ball as often as he desires, and yet not disturb the growth. The rim of the top should not project far, or the pots occupy too much space. The hole at the bottom should be well protected with broken crocks, oyster shells, coal cinders, or stone chips, covered with moss, so as to preserve good drainage. These pots are of all sizes, from "thumb pots" holding half a gill up to several gallons. The thumb pots suffice for *starting* single plants—and cost scarcely a dollar a hundred.

Chicory.—C. H. S., Clay Co., Ill., asks, "How shall I cultivate chicory for use, instead of coffee?" Sow early in April, in good warm soil, in rows 16 inches apart. Keep the ground loose and weeded, and thin to 4 to 6 inches apart. The culture is similar to carrots or parsneps. Dig when the plants stop growing.

Gooseberry and Currant Wines.—Dr. A. Noyes, of Bangor, Me., sends us half a dozen bottles of wine, made from gooseberries and currants in 1859. To each quart of juice were added 2 quarts of water and 2 pounds of sugar. The mixture was then put into casks, filling them up. The bung-holes were left open until fermentation had nearly ceased, and then closed, not perfectly tight. The samples received were: 2 from red currants, 2 from white currants, and 2 from gooseberries, All are good; those from gooseberries very agreeable; but all rather spiritous, from the amount of sugar used.

Sassafras Bark a Remedy for Worms in Dried Fruit.—Dried apples, peaches, and other fruit are usually infested with worms, if kept for a long time. S. S. R., sends the *Agriculturist* his plan of keeping them. "Put in common muslin bags with a little sassafras bark scattered through, a handful of bark to a bushel of fruit, and no worms will trouble them, as I have proved by keeping dried apples 2 years in a pantry."

Soiling Sheep.—A., Millmersville, O., inquires if sheep will do well if kept up and fed green hay in the Summer time, instead of being kept at pasture. When sheep are "kept up" in the Summer time, they are commonly fed dry hay and other food, much as in Winter, and they do well. If any of our readers have experience in this matter, we hope to hear from them.

Extraordinary Mutton.—Two Cotswold ewes imported and fattened by S. W. Buffum, Winchester, N. H., raised lambs at 1 and 2 years old, but not since, in 1860, weighed 350 and 356 lbs., respectively—690 in '61, 575 and in '62, at the time of their slaughter by Bryan Lawrence, Centre Market, N.Y., one *reported* 329—dressed **208 lbs.,** the other 321—dressed **215 lbs.** They were 5 years old. Mr. Lawrence sends one of them to President Lincoln, the other to Secretary Seward, in token of his appreciation of their services to the country. They are, so far as we can learn, the heaviest sheep ever killed in this country.

John Sanderson's Ox. "Constitution." We gave in the February *Agriculturist* (page 57), the measurements of this monster grade Short Horn Steer, not knowing that he was then on his way to this City, and to slaughter. He was purchased, exhibited, and finally killed by Bryan Lawrence, Centre Market, in whose hands we examined him before his slaughter, and from whom we obtain the following figures. Live weight 3,300 lbs., (having fallen off considerably since his 150 mile journey). Dressed weight as follows; Quarters, fore, 743 lbs., and 732 lbs.; hind, 496 lbs., and 502 lbs. Total of carcass, **2,473 lbs.** Hide 125 only, and Tallow 147. These figures show, so far as we know, unprecedented excellence. A heavier carcass than was ever before seen in New-York, (or elsewhere in this country we believe), of unexampled fineness; with smaller offal, lighter hide, smaller loss than we have ever known, and in connection with so large an animal. The beef or proceeds of its sale are to be distributed among the poor of the City.

Smoke Stains on Marble.—Some one at Prince's Bay, who signs himself "Anti S. of Essex," in referring to the item on page 38 of February *Agriculturist*, writes: "Make a solution of chloride of lime in water, mix plaster of Paris with it to the consistence of paste, and apply to smoke stained marble. It will remove stains with no injury to the polish of the marble."

Feeding Value of Chess and Cockle Seed, and Corn Cobs.—Isaac Bachtel, of Stark Co., Ohio, states that many farmers use the screenings of their grain, and asks for the per cent. of nutrition in chess, cockle, and corn cobs.—No chemical investigation has yet been done. Of chess and cockle we can only estimate that could now be made must be derived from the results of their use, and no one ought to grow enough of these pests to make it worth while to inquire into the subject. Corn cobs vary greatly in value according to the ripeness of the corn when cut. The analysis hitherto afforded is not much at any time, though as a divisor of meal, or to "fill up," we incline to the opinion that it is well to grind the cobs with the corn for working animals. They are probably as good as their weight of fine chopped dry straw.

The Largest Pumpkin—A Gourd Exhibition.—There has been on exhibition for three months past, at the office of the *American Agriculturist*, the largest pumpkin we have ever seen, and perhaps the largest one raised in this country. It measures 7 feet 2 inches in circumference, and weighed at first 204 pounds. It was grown by Mr. Geo. Barclay, of New-Hamburg, Dutchess Co., N. Y. Decay appears to be setting in, and it will need to be removed soon. The largest pumpkin we have seen noticed in Europe, was one of 262½ lbs., and more than 10½ feet in circumference, raised at Orleans, France; and one of 220 lbs., and 8½ feet round, grown at Paris last year. In England, pumpkins and gourds are classed together as gourds, but divided into "ornamental," "eatable." There is to be a grand Gourd Exhibition, including the two classes, by the Royal Horticultural Society of London, next October, when there will doubtless be some big things shown, both from Great Britain and the Continent. We fear the show will be too early for the exhibition of fully matured specimens from this country. Perhaps we may be able to compete if plants are started early, in hot-beds or green-houses. We may add, in this connection, that some Belgian growers are preparing to ensure the growth of pumpkins by feeding the plants with milk and water—the fluid to be supplied by a rag leading from a vessel, and inserted into the peduncle (fruit stem) of the plant. At least so it is reported. We suspect, however, that the report arose from the practice of hanging a rag from a vessel of this nature water, so that it should constantly drop down upon the soil near the roots of the vine.

The N. Y. State Agr.'l Society, held its Annual Meeting in the Assembly Chamber, at Albany, on February 12th. The Treasurer's Report showed expenditures amounting to $18,179 and a balance of $42 on hand. The following officers were elected for the year: *President*, EZRA CORNELL, of Tompkins Co.; 8 *Vice Presidents*, viz.: Thomas H. Faile, of New-York; Samuel Thorne, of Dutchess; Herman Wendell, of Albany; Oscar Granger, of Saratoga; Solon D. Hungerford, of Jefferson; Thomas I. Chatfield, of Tioga; Patrick Barry, of Monroe; Samuel W. Johnson, of Cattaraugus; *Cor. Sec.*, Benjamin P. Johnson, of Albany; *Rec. Sec.*, Erastus Corning, Jr., of Albany; *Treasurer*, Luther H. Tucker, of Albany; *Executive Committee*, T. C. Peters, of Genesee; E. Sherrill, of Ontario; A. Hubbell, of Oneida; C. I. Hayes, of Otsego; W. Newcomb, of Rensselaer. Dr. Fitch was ill and prevented from presenting his report on Insects, but a letter was read from him on the Entomological results of the past year, and Mr. H. S. Randall read a valuable paper on fine wool sheep in this Country.

"Association of Breeders of Thoroughbred neat Stock."—This Society was formed to enable breeders to gain a fuller and truer knowledge of the stock of the country claiming to be thorough-bred, of *all* the recognized breeds, and to promote the improvement of the same. The pedigrees of the animals of the members are recorded after thorough investigation, and it is supposed that none but flawless pedigrees can be found upon the books of the Society. The records of Ayrshire cattle are so full that we presume the Society will at once commence an Ayrshire herd-book; and as the publication of the Devon herd-book has been so losing a business that Mr. Howard proposes to discontinue it, this Association will very greatly favor the public by continuing this publication. See advertisement of Annual meeting.

Transactions of Agricultural and Horticultural Societies for 1862.—We acknowledge the receipt of the 45d Annual Report and Transactions of the Hampshire, Franklin, and Hampden Agricultural Society of Mass., from the President, T. G. Huntington, Esq.——Of the 9th Annual Report, Transactions of the Worcester North Agricultural Society, of Mass.——Of the Transactions of the Jefferson County Agricultural Society, of N. Y.——Of the Transactions of the Mass. Horticultural Society, from Eben Wright, Corresponding Secretary.

Geological Survey of Michigan.—We are glad to learn from a copy of the First Biennial Report of the State Geologist, Prof. Winchell, that this survey is in progress; but the appropriations are too limited for the importance of the subject. A hundred thousand dollars expended in this work during the next three years, would be the best possible investment that could be made towards developing the resources of the State, and the money would come back almost every year if not offence. If the mass of the people fully understood the object and advantages of a thorough examination of the *soils*, minerals, salt springs, coals, fertilizers, etc., one, or two, or three hundred thousand dollars would be cheerfully set apart for the work. We are happy to be able to assure them that under the supervision of Prof. Winchell, the work will be well done. We speak from personal knowledge of his ability, and integrity.

Farmers' Clubs and Sewing Societies.—"Charley Clover," of Elizabeth, N. J., writes of the success, patriotically, practically and socially, of the meetings of ladies to aid the Sanitary Commission, which meetings were attended by the gentlemen in the evening. The institution has promoted the Union cause in so many ways, and is regarded with so much favor, that we suggest the formal publication of the *basis of union* between the Farmers' Club and the Sewing Society.

An Important Enterprise—The Co-operation of all our Readers Asked.

The project detailed below is one of general interest, not only to each of our readers, but to the whole country, and we ask special attention to the subject. It is well known that in this country we have no public system of gathering from year to year, and at different times in the year, *the statistics* of the *condition and probable yield of our growing crops*. This work should be done by the General Government, but at present it is not, nor is it likely to be for a year or two at least. When, for example, the wheat harvest approaches, there is the utmost uncertainty, not only as to the relative *amount* sown, but also in regard to the *condition* of the growing crop. Shrewd speculators, who have on hand a large stock of old grain, often circulate newspaper reports to the effect that owing to bad weather, insects, small breadth, etc., there will not be half a crop gathered. On the other hand, as the harvest begins, another class intending to become grain buyers, are interested in magnifying the yield for the purpose of depressing prices. Thus, not only the producers, but many dealers themselves, are in a state of doubt and uncertainty. Some farmers, influenced by one class of reports, hasten to sell their grain at any price they can first get. Others, seeing more of the other kind of reports, hold on tenaciously, hoping that, owing to the reported poor yield, they will realize higher prices than their neighbors. In short, there is such an entire absence of reliable statistics that all are in a state of doubt and uncertainty, and none more so than the non-commercial producers. This state of things we propose to try to remedy, to a small degree at least, if we can secure the aid and co-operation of our readers, in the following manner:

1. Let the readers of the *Agriculturist* in every town counsel together, and select some man who may be relied upon for good judgment, and general ability to estimate with some degree of accuracy in regard to the leading crops, wheat, corn, etc., (*a*), what is the amount of surface sown or planted, as compared with previous years; and (*b*), the *prospect* at any date. Wherever there is a Farmers' Club, let the Club choose the reporter. Let it be understood by him that he is desired to keep on the look-out, and be able to respond to all questions as to the prospect of the crops. Where any subscriber stands alone, and can get no one to cooperate with him, let him volunteer to act himself, and the very fact that his report is to go out to the country will lead him to be observant and make inquiries.

2. Let the name of such persons be forwarded to the Editor of the *Agriculturist* without delay.

3. To every such person we will send out a sheet of *blank forms*, to be filled up with a brief summary of the amount and condition of the leading crops of the different kinds. The blanks will be so arranged as to require very little writing in filling up, and therefore involve but little labor aside from that required to be well informed as to the condition of the crops.

4. One of these blanks to be filled up at given dates, say May 10, June 10, July 10, and August 10, and forwarded to this Office.

5. These reports will be published in tabular form in the *Agriculturist*, either in full or in a well digested summary.

It will be seen at a glance, that such a system of reports will be of immense value, not only to the country at large, but to every man who has produce to sell. Suppose that only five hundred or one thousand such reports should be gathered and published; yet, if they come from different parts of the country, it is evident that they will give at least an approximation to the average of the whole country. The reports should embrace a neighborhood, and not merely the reporter's own crops, for their condition may depend upon his own good or bad husbandry.

Such is the plan we propose. It will involve much labor and expense on our part, but we shall cheerfully undertake it, if our readers will so far co-operate as to present us with the names of reliable men upon whom we can call for the desired information.

Please act upon it at once. We desire *only one name at a Post-office*. When there are several subscribers at any office, and this is generally the case, let those who first happen to meet, talk the subject over, and in conjunction with others, select the man, and then some one send us his name and address. When there is but one subscriber, let him talk over the matter with his neighbors who are not subscribers, and among them agree upon some one to act as reporter. It is not at all essential that the reporter be a subscriber. What we desire is, the best man to fill up the blanks and return them to us. On receiving his name, we will enter it among those to whom blanks will be forwarded, with instructions how to make up the report. Since "what is everybody's business is nobody's business," will the reader of this please make this matter one of his own affairs to be first looked after. It needs no argument to show that such a system of reports will be valuable to every farmer, and that, since every other interest depends mainly upon the prosperity of agriculture, (as we clearly demonstrated last year,) all classes will be interested in getting the earliest and most reliable reports of the general condition of the incoming crops of the country.

Farmers' Prospects—What of the Future?

Could we spare the room, it would be pleasant to publish extracts from numerous letters which speak in strong terms of the articles on the market prospects, published in the *American Agriculturist* during the past eight or ten months. These statements voluntarily made, indicate that this journal has saved to its readers, in a single year, vastly more than it has cost the country during the whole twenty years of its existence. Multitudes speak of having realized ten to thirty cents per bushel more for their grain, than they would have received, had they not been induced to withhold their produce from market at a time when prices were at the lowest ebb, and when men's minds were filled with fearful forebodings. So much for the past. The object of many of the letters referred to is, to draw out some definite prognostication from us for the coming year. But here we find ourselves very much in the dark, for the time being. We will, however, offer some general suggestions:

1st. The deficiency in Europe is not yet supplied, and will not be fully met for months to come. In short, if every bushel of wheat that can possibly be spared throughout our country, be gathered up and sent to the seabord before the first of next June, England and France will take it all, and ask for more. The foreign stock of breadstuffs is rapidly decreasing, and we look for very large orders as soon as they can be filled on the opening of inland navigation.

2d. The present indications are, that *after* the next harvest the foreign demand upon us will be very small, if it do not entirely cease for a time. Last Autumn the season for sowing winter grain was very fine, both in Great Britain and on the Continent, and especially in the former, and the breadth sown was greatly above the average. Up to the date of our latest foreign reports, the winter weather had, on the whole, been favorable. Unless, therefore, the spring weather should chance to turn out very badly, so much so as to injure the winter grain, and interfere with the sowing of spring wheat and other spring grains, we can not look for much foreign help in our grain markets *after* June.

3d. In this country it is yet too soon to hazard even a "guess," as some of our readers ask us to do. The breadth sown last Autumn was not much, if any, above the average. It was generally got into the ground in good condition, however. Thus far the Winter has not been the most favorable. There has been too little snow to protect wheat well, and it has still to run the gauntlet of the warm days and freezing nights of March and early April. Wheat will stand the most intense steady frost far better than the expansions and contractions of the wet soil produced by cold nights and warm days. The weather from May 1 to harvest, insects, and dry weather at the time of gathering, may make half difference in the yield. All these circumstances taken into account, we shall hardly look for more than an average crop at best. And moreover, the fact that we had so large a yield in 1861, is rather against a similar yield in 1862, judging from the ordinary course of Nature.

3d. To counterbalance, in part, the expected cessation of a foreign demand, we shall have the fact that the country will be entirely drained of old stocks of grain—probably more so than at any harvest for several years past. This, of itself, will have a favorable effect upon prices, and should the yield turn out below an average, prices will be likely to rule high. One practical conclusion to be drawn from the above statement is, that farmers should prepare to sow a large breadth of Spring wheat.

4th. Much will depend upon the course of the war, and the financial policy adopted by Congress. We look for the termination of the war within a very brief period. It may extend into the Summer, and perhaps into Autumn, but this is scarcely probable. The restoration of peace will be likely to be followed by a sudden spring in all business operations, activity in manufactures, and high prices for all kinds of farm produce. A collapse will, perhaps, or probably, follow, and it behooves farmers, at least, "to make hay while the sun shines." If the country be flooded with a large amount of Treasury Notes, the price of everything will go up in proportion to the relative amount of circulating medium. It will be a good time for farmers to pay off their debts, and to avoid contracting new ones to be paid at a less favorable period. The most practical advice we can now give to farmers is, to prepare for the largest possible Spring planting and sowing; to save and use all the manure that can by any means be made available, and be ready for whatever may come. Do not be carried away by speculation, however high the current may run. Continue to practice the lessons of economy learned during the past dark period. Get the land and store debts paid off. Be content with present possessions, and not run into debt for more acres. Look into and develop the farm lying *under* that you now cultivate, which is already yours in fee simple.

TO THE MARKET.... From a Painting by F. Simon.

(Engraved for the American Agriculturist.)

The above spirited engraving we introduce for the pleasure of those that love to study agricultural scenes sketched by the first artists—and who does not? It suggests, also, a topic often dwelt upon in these columns, viz: the want of judgment exercised by very many farmers in selling off their *best* calves to the butcher. In our review of the N. Y. Live Stock Trade for 1861, given on page 58 of the February *Agriculturist*, it was stated that during last year there were sold in this city at the regular market yards, over *thirty three thousand* (33,388) veal calves, at an average price of $5.10 each. Probably seven or eight thousand more were sold direct to butchers, from boats and barges, and from wagons—in all over forty thousand. We stop not to discuss here whether it would or would not have been more profitable to have raised all these calves. The value of milk in and near New-York would probably decide the question in the negative. The point we would here make is this: A considerable number of these calves were "bobs," or "kittens" as they are called in market parlance, that is, calves two to six days old, which sold to some of the lowest class butchers at $1 to $1.50 each—sometimes $2. Taking out these, the average would range near $6 a head. Now, very many of these calves were large noble animals, that sold for $8 to $10 each, and these are just the class that find the most ready sale, and, we are sorry to say it, the class that farmers are most ready to part with, because they can get two or three dollars more a head for them. But it costs scarcely any more to raise to three years of age one of the best calves, than one of the poorer ones—indeed it often costs less. Yet at three years old the one animal will be worth ten to twenty dollars more than the other. It needs no figuring, no further argument, to indicate lack of economy in the present system. It is on a par with the following: Two brothers each received 80 sheep from the same paternal flock. One sold 20 of his sheep to pay for a Southdown buck. From the 45 ewes left he raised 52 lambs, worth the next Autumn $4.25 each—$221. The other bred his whole flock to a common buck. He raised 65 lambs, worth the next Autumn hardly $3 each—$195, from which deduct $19 for keeping the extra 19 sheep, leaving $176 against $221.

Goats on Farms—Mr. Greeley's Experience.

Friend Judd.—H. G. T., in the December *Agriculturist*, wonders what can be urged against the keeping of goats. I answer—not much, if you are living on the stony hills of Palestine, or the desert of Sahara, or the Plains of Colorado, or the parched, desolate valleys of Utah, where a tree is unknown and its production is barely a possibility. In fact, I think the goat destined to prove a great blessing to all that vast region lying westward of the banks of the Platte, and eastward of the Sierra Nevada. In a shadeblest, fruitful country like this, however, the goat is a nuisance and a terror. The utmost vigilance will not prevent the destruction of your rarest fruit and shade-trees, if you keep Billy and Nanny on your premises. I speak feelingly on the subject, for my experience has been a sore one. My last trial with a she-goat (bought for her milk for an infant,) and three young ones—all fine animals, but for their invincible propensity to eat any thing that should not be eaten. I am not certain that either of them would have barked a crowbar unless very hungry; but I would not like to insure the dry, cork-like rind of the big trees of California, (from a foot to eighteen inches through,) against the teeth of any goat I ever harbored. If you must have goats, keep them, for their milk is the best food that can be had for young children; but tie them fast in some lot where nothing grows that you want to survive, or shut them up in a barn, and be sure they never have a chance of liberty. A goat at large on a Yankee farm would do more damage in a single week than can be repaired in ten years. H. Greeley.

A Talk about "Pedigrees."

"*Like produces like*" is the adage of the stock breeders; but it has some very important exceptions. Thus, for example, animals sprung from parents of different breeds, (or of no breed at all,) produce offspring unlike themselves and of no uniform type, unless they be paired with animals of some breed having *fixed* characteristics, when these fixed characteristics will generally be prominent in their offspring. A fixed or established breed is one of which the animals for many generations have exhibited the same general peculiarities, transmitting them to their progeny. The more uniformly these or any desirable peculiarities appear in any line, the more likely are they to reappear in coming generations; so certain is this, that breeders count with absolute confidence upon the value of the off-

spring of animals concerning whose ancestry they have full knowledge. This gives value to those *records* of the sires and dams of animals, running back several or many generations, which are called PEDIGREES. The facts above stated account for the great value attached to horses and neat cattle for breeding purposes which in addition to symmetry and beauty of form have excellent pedigrees. Whoever breeds from such stock feels sure that the progeny will, according to certain laws, be like the parents.

The influences of climate, food, treatment, and the purposes for which animals are raised and employed, all affect more or less uniform changes in the animals of any country where these influences have prevailed. The result is, that in each of the old countries where there has been but little change or importation of animals, the neat cattle, for instance, possess definite characters which mark them as distinct races. The same is true of sheep and swine in a marked degree, and of horses also very much in the same way, except that as horses have so much wider range than other cattle, the different races are separated more distantly, or by barriers hard to pass. So we find in Arabia, where horses are used under the saddle and valued and bred for speed alone, a race of fleet running horses. In New-England, on the contrary, saddle horses have gone very much out of use. The gait sought is the trot, and fleetness is also highly prized. We find there a class of horses bred for those ends, now becoming possessed of distinct traits and likely soon to be recognized as a definite breed, distinguished primarily for fleetness in the trot. The cows of Ayr have been bred for milk. Those of Jersey for cream. The Teeswater and Durham cattle (from which sprung the improved Short Horns) for beef. The same holds true of other kinds of animals.

Individual characteristics as well as those of the race, are communicated to the offspring, but the former less surely. When certain peculiarities are transmitted for several generations they become grafted upon the race, or rather upon the particular family in which they occur. When there are valuable traits or qualities, the value of the animals possessing them is increased. And an animal has still greater value if it can be *proved* that he draws his blood through a long line of such ancestry, because it is then certain that he has the power to impress the same characteristics upon his progeny. This, then, is the reason that pedigrees are so important, and that so much pains are taken to have them recorded in herd-books, turf registers, etc., and also to be sure that they are *true*. To give value to an animal its *pedigree* must be true, and show no mixing of the blood of different breeds, or of ill-matched families of the same breed, and exhibit a *line of ancestry* distinguished for the qualities which it is desired to have in the offspring.

Making Poultry Profitable—The Items.

In the February *Agriculturist* (article "Poultry and Pork,") may be found the results reported by Mr. J. C. Thompson of Staten Island. How he accomplishes these results he states as follows:

THE HEN-HOUSE.—Mine is a lean-to—10x16 feet—10 feet high on the rear and 8 feet front, facing the South. A barn stands on the East end; a shed on the West end, with a glass front, for a shelter and feeding place in cold and wet weather. The roofs of both project three or four feet, which keeps the ground dry in front and about the entrance. The back and front of the house are lined, or double boarded, and the front has three glazed sashes—furnished with inside shutters—a ventilator 16 inches square is placed in the roof, with a valve hung at the bottom, to close, more or less, as may be required, in cold and stormy weather.

ROOSTS.—A frame is made and hung to the rear of the house, which can be set at any desired inclination; the roosts are placed lengthwise on the frame, ladder-like, about 18 inches apart. As all fowls seek the highest roosts, these are filled first, and others in succession. This brings them close together in cold weather. In warm weather the frame must be leveled to make them scatter on all the roosts, and keep cool as possible. The floor being concreted, it is easy to clean, keeps out rats, and makes it dry. Under the roosts I place fine charcoal (a poor plan to use charcoal—ED.) or dry earth, or muck, to absorb the droppings; a few shovelfuls added each day keeps the house free from any bad odor. The rest of the floor should be covered with saw-dust, dry earth, chaff, or cut straw, for, in cold weather, hens like to keep their feet dry and warm. Neither *coal* nor *wood ashes* should be put in the house, as they act on the manure, and decompose the uric acid, thus wasting ammonia, and making the house offensive.

FOR NESTS—Use butter or lard tubs (which can be had at the grocer's for 6 cents each) set on shelves at the ends of the house, one to two feet from the floor—portable nests (with glass nest eggs) are best. They should be often cleaned and supplied with fresh straw or hay. The grease on the tubs is a remedy against lice. [A good idea.—ED.] Greasing the roosts at all the places where they touch the frame, and in fact, the inside of the house and roosts, with any kind of soft grease or fish oil, is certain to destroy them, as they cannot live a moment in grease. A paint brush or white-wash brush can be used for applying the grease, which should be done early in the Spring, and again in Summer, if it appears to be required.

MODE OF FEEDING.—I give only sound grain; no other should be used. A variety is not objectionable. My standing dish is wheat screenings; this is always by them, in a box slatted up at the sides for the purpose, as a feeding box. In Winter scalded corn meal or ground corn and oats is given to them warm in the morning; but the main food must be hard grains. They must be well supplied with finely cracked oyster shells, gravel and mortar, and green food in Winter. Mine consume two or three heads of cabbage daily. They get the scraps from the table, scrap meat, etc. In Summer, grass, lettuce and cabbage are furnished daily in abundance—they will consume a great quantity.

YARD ROOM.—The permanent yard is 50x50, opening into a grazing and rambling lot of 50x100, also used as a plum orchard. The fence is only 5 feet high, and by feeding well and clipping the feathers on one wing, there is no trouble in keeping them at all times within the yard.

SETTING THE HENS.—To insure good healthy chicks, the hens should be set in March, and certainly not later than April. By having portable nests, when hens desire to set, and become fixed in the habit, in the setting season, they can be supplied with eggs, (the date of setting marked on them in ink or pencil,) and any number of nests moved to a room for the purpose, which must be kept closed, and well supplied with food and water. The nests may all be set side by side, for if the hens should all leave their nests at once, to feed, when they return they will each take a nest, although they may change places. This arrangement insures their setting steady, as they are not compelled to wander off for food, but return quickly to the nest, and keep up the warmth of the eggs, and thus bring out strong chicks. By setting a number at one time, if some hatch half broods, they can be put together with one hen. When a setting hen looks pale about the head, it is evidence she is lousy; clean and wash the nest, grease the hen under the wings, on the back and rump, wash the eggs in warm water, and return to the nest. [Better transfer to a new, clean nest.—ED.]

TREATMENT OF CHICKS.—When first hatched, they must be fed on bread soaked in milk; after three or four days, feed with cooked or scalded Indian meal, three times a day; but finely cracked corn, or wheat screenings, should be always within their reach; also clean water. The hens with chicks should be kept in coops for several days, the coops kept dry and clean, and placed in sheltered places. With such treatment not five per cent. of chicks will be lost. In conclusion let me say, the secret of success with fowls is this. They must be *young, well fed*, and *cared* for, and small numbers, 15 to 25, pay much better in proportion than large flocks.

J. C. T.

What does it Cost to Keep a Horse?

We would be pleased to receive for the *Agriculturist* some brief accurate statements, going to show the average cost of keeping a horse for a year in different parts of the country. As the market value of grain and hay varies greatly, it will be best to give the average amount of each kind of food consumed by two or more horses. As a guide we present the following items from an English Farmer's Note Book. The table gives the yearly *average* for 6 horses, during a period of 8 years.

Average Yearly Expense of each Horse.

64⅝ bushels of Oats, @ 62½c	$40.31
1 tun of Hay in Spring	15.00
2 tuns of Straw and Chaff, fed in Winter	10.50
9 weeks Pasturage in June and July	9.00
Harness and Shoeing	5.25
Average yearly loss by age and death	22.21
Annual Cost per horse	$105.97

This is estimating at English prices for food. The horses were valued at $110 each. During the 8 years 11 horses were lost by various diseases and accidents, making a total loss of $1,210, or $151.25 per year, or $25.21 on each horse. As 11 new horses were purchased during the 8 years, it is probable that the stock was as good at the end as at the beginning of the period; but about $8 should be allowed for the annual interest on the value of each horse. Each horse averaged 258 days of farm work in the year. Merely for example, let us make out two similar tables for this country, taking the same amount of food, but substitute one tun of hay for the two tuns of straw and chaff, and allow four months pasturage.

Yearly Cost of a Horse in more expensive Localities.

64 bushels of Oats, @ 40c	$25.60
2 tuns of Hay, @ $14	28.00
17 weeks Pasturage, @ 50c.	8.50
Harness and Shoeing	5.00
Annual Loss per horse	22.00
Interest on Value	6.00
Total Cost for a year, say	$100.00

Yearly Cost of a Horse in less expensive Localities.

64 bushels of Oats @ 20c	$12.80
2 tuns Hay, @ $8	16.00
17 weeks Pasturage, @ 25c.	4.25
Harness and Shoeing	5.00
Annual Loss	20.00
Interest on value at say $100	7.00
Total Cost for a year, say	$65.00

As above hinted, these tables are not given as accurate, but merely as a form for the guidance of such as may be disposed to furnish more definite information from their experience.

Farmers Wide Awake.

There are all sorts of farmers in the world, and they, accordingly, meet with all sorts of success. There are intelligent, enterprizing, industrious, economical men; and over against these are ignorant, shiftless, wasteful men, who are seldom prosperous. If the lack of activity and thorough business habits which prevails in many of our farming districts, were suddenly transferred to our large cities, and made to pervade our bankers, merchants, publishers and tradesmen, what a shock it would give to the wheel of commerce! Many a door would soon be closed by the sheriff, and grass would grow in our streets. Manufactures and trading generally are conducted with carefulness and economy, with constant attention to details, watching against losses, seizing upon all possible advantages, and with an industry that never tires. This and this alone is the royal road to success.

Now, agriculture, to be prosperous, must be conducted in the same way. The farmer must be a shrewd, thinking man, one who knows at least something of the theory and much more of the practice of his calling; knows how to bring his lands into the best possible condition and to keep them so; knows how to take advantage of the market; how to get the best returns from a given amount of money and labor; knows how to economize, and how, at times and as wisely, to make large expenditures, (say, in draining, manuring, etc.,) when they are demanded. For, in farming, as well as in acts of general benevolence, "there is that giveth and yet increaseth; and there is that withholdeth more than is meet, and it tendeth to poverty."

It is the importance of sagacity, prudent forethought, and management, of skill and enterprize that we wish now to inculcate. More muscular labor, however severe and unremitted, is not enough; book learning is not enough, if disjoined from industry, tact and economy. There is an ideal in every farmer's life, towards which he should always be striving to approach. He should aim to be a man of general intelligence. Aside from the topics of reading and study common to every well-informed man, it becomes him (and it pays) to be familiar as far as possible with practical chemistry, meteorology, geology, mineralogy, botany, animal and vegetable physiology and mechanics. Surely, there is no need of mental inactivity here. Nor should he be merely a man of books and 'ologies. He ought to be a practical, sound-minded, industrious, common sense man, as familiar with all practical details as with theories. There are already many such farmers: we only wish there were more. And ere long, there will be.

How a Woman's Perseverance secured a Fine Homestead.

To the *American Agriculturist*, from one of our German subscribers in Tipton County, Ind., and is but an imperfect picture of what has occurred, and is still occurring, in many western localities:

"About twenty years ago a young couple came here, and bought 160 acres. Though the price was low, the purchase money nearly exhausted their means. They began with hard labor to build themselves a future homestead, and through all the hardships of their undertaking, the young wife was at the side of her husband, and even shared his out-door toils. One day, when they were both trying to fell one of the big oak trees, the man, exhausted and discouraged, said: "I think we had better give up, and try some other business, we will never succeed in this." Thus saying, he put down his ax. But the woman was not so easily disheartened. "Oh! cut away!" she said, "we will conquer these trees by and by, and we *will* have a nice farm before long." These words gave new strength to the man's arm, he commenced to work again. Now, in 1861, they have a beautiful farm of 200 acres. They are 'well off,' as people say. At the county fair the woman received premiums for her fine apples and grapes. The daughter had good needlework there, and the father exhibited excellent horses there, and the father exhibited excellent horses and mules. He has a thousand bushels of corn in his crib. He reads the *Agriculturist*, and procures good books for his wife and children to study. The husband often relates the story to a circle of friends, and says that he would not have had this farm and independent homestead, but for the perseverance and encouragement of his wife on that day."

Washes for Trees.

Complaints are made, here and there, that certain washes for the bark of trees do more harm than good. One, whose apple trees were mossy and hide bound, and infested with insects, used lime-wash; another used soap; another tar; another, a solution of potash; but in nearly every case, with unsatisfactory results. The caustic lime kills the parasitic plants and the vermin which infest the bark; but while a good part of it soon washes off, what remains becomes converted into carbonate of lime, which fills the pores of the inner bark, and prevents its healthy expansion and growth. Common soap suds is less hurtful than the solutions of caustic potash or the tar.——The safest and best wash known to us, is simply a solution of common salsoda, (often called bleacher's No. 1 soda,) dissolved in rain water, at the rate of one pound of soda to a gallon of water, and applied in Spring and Fall. It will not hurt the tree, but will destroy mosses and other fungi; and no eggs or cocoons of vermin can stand before it. It will work off the dead bark, and leave a clean and healthy surface. But to ensure the highest success from this application, the soil about the roots of the trees should be drained if it is wet, and be manured if it is barren.

To Exterminate Pea-Bugs.

"What shall I do to rid my peas of bugs?" exclaim both gardeners and farmers. And we will attempt a reply. The pea-weevil, a small, brown bug or fly, appears early in the Spring, at the time the first crops of peas are forming their pods. He stings the tender pod, right against the nascent pea, and deposits an egg. Sometimes he punctures every pea. A grub is soon hatched, which eats his way into the heart of the pea. Here he grows apace, and by the time the pea is ripe he is full grown, about an eighth of an inch long. He is now a white grub, and has eaten out nearly one half of the pea. His next step is to pass into the pupa state, where he remains until the last of autumn, when he becomes a black beetle, and is prepared, on the opening of Spring, to attack young peas and to reproduce his kind. This being the natural history of the insect, we may judge when and how to attack him. The black-bird, crow and oriole are his born enemies, but they do little towards exterminating him. Of the several methods employed successfully, here is one: Make as many wooden boxes as you have varieties of seed, and fit them with tight covers. After gathering, sorting and drying the seeds, put three or four bits of camphor, the size of a pea, into each box, shake well together and put away. The bugs will be disgusted. Another way is, to scald the seed for about half a minute in boiling water, just before planting. This will, at least, destroy the grubs in the seed. If peas are buggy, we usually take our seed, a peck at a time, and just before sowing, pour in boiling water enough to cover them; then stir until cool, and sow. The scalding has never appeared to injure the germs, while it utterly destroys the bugs, and hastens the sprouting. If too large a mass of peas be taken together, or if rapid stirring be omitted, they might be injured by the heat.

Another is this: Gather the peas as soon as ripe, dry them for two days in the sun. Then put, about a pint at a time, in a colander, cover with a pan, set them over a vessel of boiling water, keeping them there until the steam has penetrated the whole mass of seed. Then spread them out to dry, and put away in boxes or papers. This will kill the pupa, while it will not injure the germ of the seed.

Peas sown as late as the middle of June, are seldom infested with the weevil, because its period for depositing eggs is then past. It is a common and good practice to sow peas for the next year's seed very late in the season.

Birds and Insects—Striking Figures

Prof. Treadwell of Cambridge, in a recent communication to the Boston Natural History Society, relates the following gastronomic feats of the Robin redbreast. "By experiment it appears, that though the bird's food was increased on the 11th day to 40 worms, weighing 20 pennyweights (1 ounce), the weight fell off; and it was not until the fourteenth day, when he ate sixty eight worms, or 34 pennyweights, that he began to increase. On this day the weight of the bird was twenty four dwts.; he therefore ate forty one per cent more than his own weight, in 12 hours. He weighed after it 29 pennyweights, or 15 per cent less than the entire food he had eaten in 12 hours. The length of these worms, if laid end to end, would be about fourteen feet, or ten times the length of the intestines. To meet the objection that the earth worm contains but a small amount of solid nutriment, on the twenty seventh day he was fed exclusively on beef, in quantity 23 pennyweights; at night the bird weighed 42 pennyweights, or but little more than twice the amount of food consumed during the day—not taking into account the earth and water swallowed. This presents a wonderful contrast with the amount of food required by the cold-blooded vertebrates—fishes and reptiles, many of which can live for months without food. It contrasts also with that required by mammalia. A man, eating at the same rate, would require about seventy pounds of flesh a day, and drink five or six gallons of water."

We think few were prepared to believe such facts in regard to the robin, whatever may have been their impressions of the usefulness of this bird. A pair of these birds in a garden, with the average of four young ones, would eat two hundred and fifty worms, or their equivalent in other insects, daily! Of canker worms and caterpillars when they first come out, this would amount to several thousands daily. It would not take a great many birds to keep a garden clean at this rate. We have heard of men who

boasted that they could whip their weight of wild-cats. The robin not only whips his weight of savages every day, but destroys them and converts them into excellent guano.

There can be no doubt that Providence intended birds as a police to keep the insects in check, and if we will keep the cats and boys under, and give the birds a fair chance, we may again have plenty of fruit and grain.

Celery as a Field Crop.

A New-Jersey market gardener communicates to the Gardener's Monthly the following method of growing celery, which he represents as being easy as raising a crop of cabbages:

"The ground necessary for the growth of celery need not be damp, as is generally supposed. Any good, rich vegetable soil, if level, is sufficient. Although the plant luxuriates in moisture, if properly applied, yet it is as quickly impatient of stagnant water at the roots as almost any other vegetable. One of the best varieties for private culture is the Incomparable Dwarf, a solid, white variety, never attaining more than two feet in length, but of the most delicious flavor. This variety is particularly well adapted to this simple mode of cultivation, which consists in planting the plants on the surface, one foot apart *each way*, so as to form a square bed. The object in having the plot thus square or oblong is, that when the celery is so planted in a mass, the plants crowd each other when full-grown, so that in the struggle for light, the hearts are drawn upwards—one of the most important objects to be attained; which, when the celery is planted in single or double rows, can not be attained, without the processes of what we call "handling" and "hoeing up." The time of planting is usually the month of July; but if good strong plants can be had, fine celery may be grown by planting in August. Nothing further whatever is necessary in its cultivation but simply hoeing to encourage growth and keep down weeds, as is done in a cabbage or onion bed. This, then, is the whole process from the time of planting in July until November. Thus far, it is, of course, green, unblanched; the blanching process being done when stored in winter quarters.

The time of digging up of course varies somewhat in different localities. In this district we usually have all put away by the middle of November; and after ten years' experience, we find no plan so simple or so safe as the trench system for blanching or preservation.

The process consists in digging a trench or drain ten or twelve inches wide, and of the depth of the length of the celery. The celery is then packed *perpendicularly* in the trench, moderately tight, until the whole is filled up. It will be understood that there is no soil thrown in about the roots—none being necessary. The roots, being at the bottom of the trench, quickly absorb sufficient moisture to encourage new roots, which, as soon as formed, the blanching process is begun, and the celery will be fit for use in four or six weeks from the time of being put in the trench. It is indispensable to cover the trench with leaves or stable litter to the depth of six or eight inches; but this must be done gradually—two or three inches at a time—as the season advances. If put on at once, it stops the evaporation from the mass of celery packed in the trench, and the blanching being prematurely hastened, it will not keep so well. A great advantage we find in this way of preserving winter celery, is in the easy access we get to it in all weathers,—nothing more being necessary than to remove the litter and take out what is wanted, and cover in carefully again."

[A cheap easy way of raising celery is certainly a great desideratum, the above is worthy of a fair trial on a small scale. We fear the celery will not be tender.—ED. *American Agriculturist.*]

Halsted's Hand Seed-Drill—Not Patented.

We present below engravings and a description of a new Seed-Drill, on exhibition at the Office of the *American Agriculturist.* It was designed and constructed by Mr. A. M. Halsted, a farmer of Rye, Westchester Co., N. Y., and the implement shows a good deal of ingenuity and mechanical skill in the maker, who, in addition to the ordinary farm tools, has only a common foot-turning lathe and the assistance of a neighboring blacksmith. He constructed one at first for his own use, but it operated so well that several of his neighbors have also had them made. Mr. Halsted, however, believes in every man "sticking to his trade," and as his business is farming, he offers the plans of his seed drill freely to any or every one who desires to make them for home use or for sale, and he offers his patterns to any respectable manufacturer who will put the machines into market.

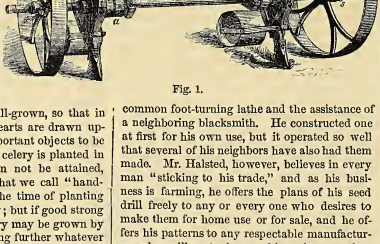


Fig. 1.

DESCRIPTION.—The size of the apparatus may be understood from the engraving—taking the wheels at nearly one foot in diameter. The letters in figs. 1 and 2 refer to the same parts. The two wheels may be fastened further or nearer apart upon the axle, being held at any point by the screws, *s*. The seed distributors are similarly adjustable, so that the implement can be used for sowing rows at different distances apart. The implement of this size and form is designed for the smaller classes of seeds. The seeds are put in the boxes or hoppers, *h*. Fig. 2 shows an enlarged section of the hopper, raised up, and of the rest of the distributing apparatus, made by cutting down through from front to rear. The seed measurers, *a*, fig. 1, (fig 2,) are little solid cylinders, with cup-like holes in the surface. These cylinders differ in the number of holes, in their distance apart, and in the depth and size of the holes—different ones being used for different kinds of seeds. The slide, *d*, is also movable up and down, so as to be made to fit the measuring cylinder more or less closely, and this increases or diminishes the amount of seed. The seed box, *c*, opens on a hinge at *g*, and is fastened down by a hook at *f*, to allow the change of cylinders. The seed drops from the measurer into the cavity *c*, and falls into the furrow made by the small hollow plow, *p*. The roller, following the plow or drill, covers the seed. The frame of the roller is attached at *k*, and the bracing rod for steadying the apparatus is fastened at *l*. All the parts are shown so plainly that further description is unnecessary.

Fig. 2.

Drilling better than Broadcast.

Drilling in field seeds is becoming quite common, but not enough so. Too many still adhere to broadcast sowing greatly against their own interests. It certainly stands to reason, that twelve stalks of wheat, or oats, or other grain, will do better if each grows on a plot three inches square, than if one such plot contain three or four stalks crowded together, while another plot has none. But this happens very frequently in a field sown broadcast. Again, if one seed be covered but half an inch, and the next one be worked down three or four inches by the harrow tooth, the two will come up unevenly, and grow unevenly. Air and sun-light are important agents in promoting the growth of plants, and the full effect of these can only be secured where the stalks are growing at something like uniform distances apart. The expense of a drill is the main objection to its introduction everywhere. But a single bushel more of grain per acre, on a ten or twenty acre field will go far to meet the cost of the drill, or at least pay a very high interest on the cost. And who doubts that much more than the extra bushel will always be secured by judiciously using a seed drill.

About Farm Implements.

It is "penny wise and pound foolish," to buy poor implements because they can be got *low.* Such will cost a vast deal of time and patience, and no little money to keep them in order, and even then not work satisfactorily. Moreover, there is a great deal of pleasure in using a machine or simple tool of the best make, not because they are expensive, but because they are handiest, and on the long run they are the best and cheapest. The interest at ten per cent is only $1 a year on an implement costing $10, while it is 50 cents on one costing $5. Very often the $10 implement will save half a dollar a day over the $5 one, by its better work, and saving of man and team power. Nor is this all that is important about implements. When bought, they should be taken care of. Before attempting to use them, they should be put into perfect working order. The knives of a mowing-machine should be well ground, the wheels and joints oiled, and the whole gearing put into complete trim before starting it; otherwise it will get out of order, time and patience will be lost, and the whole work be done unsatisfactorily. The same is true in general of harrows, horse-rakes, rollers, plows, hoes, shovels, and the commonest tools of the farmer's carpenter shop. Have a place for everything, and then keep everything in its place, and always in good working condition. But where do we often find the farmer's im-

plements? To-day, we saw a plow standing in the furrow, and yesterday one thrown up by the side of the fence where the Fall plowing ended. Last Fall, we saw cultivators and horse-rakes dragged up into the corner of a field among the bushes. Sometimes, the expensive horse-power, instead of being carefully housed, is left out in all weathers, from one thrashing season to another. Implements so used, seldom get their iron-work oiled to prevent rust, or their wood-work painted to prevent rot. It is the testimony of all good farmers, that the time and money spent in painting their tools, is more than repaid in their increased durability. There are very few farmers who can afford to have such large holes in their pockets as this carelessness makes. One must be either very rich or be making money very fast to be able to support such extravagance. If it be true, as it is often said, that farming, as a general rule, does not yield more than five per cent on the capital invested, we do not see how any body can afford such expensive habits. And besides, such a spendthrift style of living exerts a bad influence on one's family and on the whole neighborhood in which he lives.

Blinks from a Lantern....XXIX.

VISITS RUNOUT ROGERS.

Not a dozen miles from Higgin's Rest (described in the *Agriculturist* last year), lies the farm of Runout Rogers, or what was his farm, before he sold it, for he is to vacate on the first day of April, 1863, according to the terms of sale. Just what his mother was thinking of when she named him, I am not able to say. It is not a scripture nor classic name, or one belonging to the family. He was the youngest child in the family, perhaps seen to be the youngest and last from his birth, and on that account named thus, according to a custom that prevailed in the early history of this country, of naming children from some circumstance attending their birth or infancy. At any rate, the name was appropriate and prophetic, for he has run out every thing left him by his father, and pretty much all that he has earned, so that at the age of fifty years, when a man ought to have a competence and to be looking forward to a comfortable old age, he is obliged to sell the homestead to pay his debts and square up with the world. When this little job is attended to, he will not be worth a red cent. He was left at the age of twenty three with a fine dairy farm of two hundred and sixty acres, with no incumbrance upon it except a debt of five hundred dollars due to a married sister, who had not received her portion by that amount. It was the homestead of the family, all the buildings were in good repair, and the land in good heart, capable of keeping thirty cows with all the other stock needed upon a dairy farm. It was judged to be worth, at the time of his father's death, ten thousand dollars. He had made money upon the farm, paid for it and the stock, and left, at the time of his death, an estate worth twenty five thousand dollars, which made a rich man among farmers in the last generation.

I was drawn to the place by a sale of cattle, the last remnant of the stock—thirteen cows, a yoke of oxen, and horse, being all that the farm is now capable of keeping. The sale was hastened on account of the short crop of hay, and the well founded apprehension that the crows might forestall a sale if it was put off until Spring, when such sales usually happen. The place has the neglected air of a slipshod farmer, where no repairs had been made for twenty years, beyond those which necessity compelled. Shingles will wear out, and paint will grow dingy, and fences become dilapidated in that time. The mortar had rattled out of the chimney, and the dozen displaced bricks from the top proclaimed alike the passage of time, and the breach that was made in the fortunes of the owner. The house had, originally, been painted red, and then white, in the last days of the elder Rogers. It had been innocent of oil and white lead ever since, and the red and white appeared in about equal proportions, except where the weather had effaced all traces of paint. Here and there a clapboard had entirely disappeared, and occasionally one hung by a single nail, rattling doleful music in the winter wind. The bars were generally down about the premises, and the gates unhinged. Many of the bar posts had been split and bound up temporarily with white birch withes. No walls had been re-set in the days of the present owner, and the foundations were badly hove with the frost, and the tops were full of gaps. The barn had no cellar, and no sheds; the practice of the former owner having been to winter the most of his cattle at the stack yard—a practice that the son had most faithfully followed. The cattle had been gathered in the yard for the sale, and presented a very hirsute appearance. They were exceedingly thin in flesh, the rib-bones prominent, and the back arched, probably from the habit of drawing up into the smallest possible compass during the keen winter blasts.

"What makes your cattle so fat Mr. Rogers?" I asked courteously, to draw out his views on stock.

"The Fall feed was rather better than common, and as I had not hay enough to keep them through the Winter, I intended to give them all they could eat, to get them ready to sell."

"And how long have they had full feed?"

"Well, I guess about a week. I should have begun a little earlier but I did not calculate to have the sale so early. Hay was so high that some of my creditors thought it would be worth more to sell now than to feed out this Winter."

"So you are in debt Mr. Rogers?"

"I am in nothing else," he replied sorrowfully, "and never have been. You see I was in debt five hundred dollars when I begun, five and twenty years ago. But I had a large farm, and a good one, and it used to bring in crops and produce worth fifteen hundred dollars a year, so that I had enough of every thing, and did not pay any particular attention to the debt. I could have paid it then easy enough, in two or three years, but I let it run without paying the interest. Somehow the farm did not produce as it used to when father owned it, though I did every thing about as he did only I did not make so much manure, as I always thought it cost more than it came to, to cart dirt into the barn yard, and then cart it out again. After a few years I found I did not bring the year around without getting in debt, and I had to hire money to pay up my store bills. The seasons seemed to change, the Springs were backward, and the frost come early in Autumn, killing the corn and spoiling the after feed, and I have had to reduce my stock and get in debt, until every thing is mortgaged, and I have now had to sell out entirely to get square with the world. Don't you think the land is running out round here?"

"I rather think *men* have run out." I replied, bringing the glare of my lantern full in the face of Mr. Rogers. The man looked blank, probably not half comprehending my meaning. But here it is—the same old story over again—the soil ruined for the want of brains to till it. You talk a great deal in the modern age about improved implements of husbandry and improved tillage. The greatest want of all is improved men. A *man* in the place of Runout Rogers would have kept this old homestead improving, so that it would support a hundred head of cattle. The soil has run out for want of a man to till it.

If I might trace the process by which he has lost his farm, I should say his first error was that he has paid no particular attention to his business. Farming is as much a business as buying and selling merchandize. The merchant that never takes account of stock and balances his books to see how he stands, soon falls. Mr. Rogers never did this, and so had no reason to suspect he was losing ground until half the value of his farm was eaten up with debts.

Then he has paid no attention to manure making, which is the sheet anchor of good farming every where. With a stock of thirty cows when he took possession of the farm, he never made over a hundred loads, and it has been growing less ever since. He had all the facilities for making six hundred loads a year, and only lacked the enterprize to do it. There is a muck bed of seven acres, so deep that no bottom has ever been found, within a quarter of a mile of his barn.

Again, he has sold grain and hay instead of feeding it out upon the farm, thus compelling a reduction of stock and smaller sales of butter and cheese, and of other animal products. His stock have had no shelter in Winter, thus costing him ten dollars a head extra for feed, and diminishing their product of milk during the Summer. His fences have not been kept in repair, and he has lost some of his crops every year by unruly cattle. The result has been, a running out process all round—less grass in the pastures, less hay in the meadow, less stock in the yard, and fewer pigs in the sty, until a sheriff's sale closes the scene. Is there not a moral in the life of Runout Rogers?

A Cheap, Strong Wind Mill.

There are many kinds of half-hard labor to be done upon the farm, more fatiguing from their constancy, than their intensity, for which some cheap power is wanted. A few of these operations are: churning, washing clothes, grinding apples for cider, mashing grapes, currants, and blackberries for wine, sawing wood, cutting hay, straw, and roots, shelling corn, etc. These are usually performed by hand labor, but it is tiresome to continue them steadily, and we see no reason why a good, cheap wind power may not be constructed, which shall take the place of manual labor. The power may be light, and even portable. It should be self-regulating, cheap, simple, and very strong in its ability to resist high winds and rough usage. Why such a mill is not in common use, is a question we refer to farmers of mechanical turn of mind, whose name is legion. We know of no such mill.

Attend to the Wood Lot.

In reference to the expediency of thinning out wood-lots, opinions differ. Some wood men hold that a forest should not be touched with the ax except when it is purposed to sweep the whole down. After this is done, say they, we may clean up our ground for crops, or may let a second growth of timber spring up. Others hold that a lot may be judiciously thinned every year or two, and thus renew the timber gradually, without ever cutting down the whole. For an old forest, where the trees have nearly made their full growth, and where there are only a few young trees, and they quite small and poor, thinning out will do very little good. The old and middle aged trees have grown tall and slender, and have got their character formed beyond much improvement. Their roots are small and run near the surface of the ground, and if we take away the surrounding trees, these slim and unanchored sons of the forest will be sure to topple over. And then, the few young trees will grow not nearly so fast, and never become so vigorous and handsome as they would in a more open situation. The better way then is to cut off the whole race, and begin anew. If the lot is fenced in, and *fires* and *cattle* kept out for several years, the young wood will make a vigorous growth, and a new thrifty forest appear with marvellous rapidity.

But suppose the wood-lot is a comparatively new one, the trees from fifteen to twenty feet high; then by all means thin out. For, when in mixed woods, trees are allowed to grow up indiscriminately, there will always be more than the ground can well sustain. Their roots will ramify in every direction, filling the soil with a massy net work, crowding and exhausting each other. Thin them out judiciously, and then there will be pasturage enough for the roots of all. The trunks and tops of those left will be better formed than they could otherwise be. A writer on forestry says that "in raising a plantation for timber, the approved rule for hard wood trees is, to leave a space around each tree equal to one-half its height; and for resinous trees, a space equal to one-third its hight. This should be kept in view from the moment the thinnings commence."

From this same source, and others, we learn that in Germany this matter is regulated by the government. Competent and educated agents are appointed, who see to it that no forest is destroyed through wantonness or neglect. They plant new woodlands, first plowing the fields selected and sometimes fenced in, and sowing the seeds of various trees. The crooked and feeble seedlings are pulled up the second year, and good vigorous ones are supplied in their places if necessary. In about ten years a radical thinning is made, only enough trees being left to just shade the ground. In this work of tilling the land and thinning the forests, a multitude of the peasantry find occupation, who would otherwise suffer for want. Shade is indispensable to the growth of the seedlings of many, indeed of most of the forest trees. When a forest is to be cut down, and re-seeded with the same kind of timber, the thinning out is carried to that extent, that but a few of the most sturdy and most fruitful of the monarchs of the forest are left. The ground then being cleared and prepared for the seed, as soon as a good mast is had, the new forest is sown—and the old trees stand a few years to protect the young growth.

Probably we should not like to have the government interfere with our forests, but the foregoing will show how much woodlands are valued abroad, and how deserving they are of intelligent care. Our own interests and those of our posterity are concerned in this thing, and we should give it our best consideration.

Pickling Wheat and Other Seeds.

Hewitt Davis, says, in the Agricultural Gazette, that his practice for many years was to use copperas, arsenic, and other mineral poisons, for preparing wheat for sowing, as a means of preventing smut, burnt ear, etc. But having lost a valuable lot of turkeys which accidentally got into a newly sown field, he was led to think further on the subject, and came to the conclusion that the benefit of pickling was mainly due to the cleansing during the pickling and washing. He has since found that the washing of grain in plenty of water floats off the impurities, and light imperfect grains, and is just as effective as the former pickling.... The editor recommends soaking the grain in a solution of Glauber's salt (sulphate of soda), which can be purchased cheaply. The grain is afterwards dried off with dry lime.....M. Leluz , of France, advises to soak wheat seed in a brine, made by dissolving at the rate of one pound of Glauber's salts to a gallon of hot water. A gallon of this is poured over each sack of wheat seed and about 2 lbs. of fresh slaked lime thoroughly mixed in to dry it off. The action of the salt and the lime is to destroy the smut and other fungi, while both together form an efficient fertilizer. We commend this method for preparing Spring wheat seed, and also for Winter wheat. The Glauber's salt (sulphate of soda) is very cheap, and can be bought in small quantities for a few cents per pound. It is sold in New-York, at wholesale for one cent a pound, or even less.

Potatoes—Small or Large, Whole or Cut.

"Big, and the but end, by all means," says one. "Cut potatoes, if you want to economize," says another. "It is of no consequence," says a third. "They will rot any way," says a fourth.

There is a great variety of practice which shows that this very useful vegetable will bear more abuse than almost any other crop grown upon the farm. The writer has tried almost all methods and has settled down upon whole potatoes, an inch to an inch and a half in diameter, as, on the whole, the most desirable for seed, taking into account the immediate crop and the future welfare of the tubers. If we look merely at the immediate crop, we can doubtless get more from a given amount of seed to cut them into single eyes, than to plant them whole. But we have very strong suspicion that this cutting weakens the stamina of the plant, and if followed up with any variety for a long series of years would run it out. We ought to follow such a method, if we can discover it, as will keep the plants in the highest health, and make the crop sure and remunerative.

We have grown good potatoes from the smallest seed, a half inch or less in diameter, but it was only upon very rich soil and with extra care. The objections to using large potatoes whole, are the extra expense for seed, as it requires from twelve to fifteen bushels to the acre, and the over stocking of every hill tending to produce a great many small potatoes. The medium size removes these objections, furnishes just about seed enough, stocks the hills sufficiently, and preserves the health of the plant. This practice we have followed for several years and on the whole, it gives the best results.

If we admit the theory to be correct on which the practice is founded, it would not follow that it would in every case preserve the crop from disease. Almost every variety has been subject to cutting and to disease for many years, and no one can be perfectly sure that he plants a sound healthy tuber if the size is every thing desirable. If the constitution has been weakened in any way it is much more likely to be injured by the hot, wet weather of August, than a strong plant would be. The universal prevalence of the rot is probably owing quite as much to the treatment of seed, as to soil and climatic influences.

Hints on Tobacco Culture.—No. I.

STARTING THE PLANTS.

Without stopping to discuss the moral question of tobacco using, we will only treat of its agricultural bearings, and here is a wide field. Exhausted acres once most fertile, impoverished farms and plantations which a few years ago teamed with luxuriant growth, whole counties and sections of States ruined as to present prosperity, testify sadly to the results of the wrong culture of this poisonous plant. This is a matter of history and fact. We hold that these results need not have been, and need not be.

Tobacco, properly cultivated, offers the farmer a very quick way of turning manure into money. The temptation is to turn also the fertility of the *soil* into money, and thus exhaust it. Few crops will bear to grow upon the same land year after year; with manure enough, tobacco may be thus raised, and as this saves labor, it furnishes powerful temptation to labor-sparing farmers. *It never ought to be cultivated except in a regular rotation.* As a cleaning crop it is valuable, for it will neither endure weeds, nor will they grow in its shade. It requires high manuring, thorough tillage, and freedom from water in the soil—so that soil on which good tobacco has been raised, is easily prepared for almost any other crop.

THE BEST SOIL is a good deep loam, and the best situation one not exposed to early Autumn frosts; first-rate corn land is good tobacco land. If broken up from sward, this should be done the Autumn previous, though by plowing early and repeatedly before the time of setting out the plants, the land may be well subdued, even if taken up in the Spring. There should be an application of manure equivalent to 40 or 50 two-horse loads to the acre—the coarser half of which should be turned under 7 to 9 inches deep, and the rest afterwards be placed on the surface, and plowed or otherwise worked in.

THE SEED BED must be prepared and sowed by the middle of April, in the warmest and best place on the farm—allowing about a square rod for each acre intended for tobacco. This bed should be deeply spaded, richly manured, and it is an excellent plan to lay on a mass of brush and dry litter and burn it, before smoothing and raking over the bed. This destroys weed seeds, adds fertility in the ashes, a dark color in the charcoal, and makes a most friendly preparation for the fine seeds. The seeds may be sprouted before sowing, by mixing them with fine earth, moistening, and setting a few days in a warm place. This is advisable only in late sowing. Use a large thimblefull of seed to the rod, if you are sure of your seed. It is always best to prove the seed by previously sowing a little in a pot

placed in a hot-bed or under a glass in the house, and kept warm. Thoroughly mix it with half a pint of fine soil before sowing; sow the seed, and then roll the bed with a hand roller, or spat it down evenly with a shovel. The bed must be shielded against frost and beating rains by covering it with boards or cloths, (hay caps are good). When the young plants appear, occasional waterings with *dilute* liquid manure promote a more vigorous growth. They must be thinned out where crowded, and scrupulously weeded. They will grow unevenly and slowly; and the largest will be ready to transplant to the field about the tenth of June, in latitude 41°—earlier at the South, and five to ten days later, if further North, at this time they may be transplanted 2½ to 3 feet apart in rows 3 feet apart. The period of transplanting continues, according to the weather, for some days, or even weeks. The young plants root easily, and grow rapidly, particularly if we have warm, moist days and, when well rooted, luxuriate in our hottest Summer weather.

[PRIZE ARTICLE.]

Cultivation of the Oat.

BY S. P. N.*

The Oat is cultivated, perhaps, more widely than any other of our grain crops, having but few enemies, tolerant of great differences of soil and climate, and producing remunerative crops on the poorest soils. Owing to its strong assimilative powers it seems one of the best means for the extraction of fertility from an almost exhausted soil. And although by some, and not a few, it is so used, yet when judiciously introduced into a rotation, it is not so greatly an exhausting crop.

PREPARATION OF THE SOIL.

It is a common custom to sow Oats following corn, although they require a rather heavier, closer soil, the desirable qualities being moistness, and a reasonable compactness; a clayey loam is the best soil, as the plant is impatient of drouth. The ground should be broken as early in the Spring as it can be *well* worked, plowing deeply, Oats being better able to bear the bringing up of a portion of the subsoil than most other crops. The teams at that time are stronger, the ground loose from the effects of the winter frosts, and the absence of sward still further favoring, it seems the most suitable time for the deepening of the soil, an object which should be ever in view with the farmer.

PUTTING IN THE SEED.

As soon as practicable, after plowing, the seed should be sown. For several reasons I give preference to drilling in the seed, for by so doing (1st,) the seed can be more evenly distributed than by hand sowing; (2d,) the covering is more perfect and uniform than either by the harrow or the plow; (3d,) the amount per acre can be more exactly regulated; (4th,) the grain comes up simultaneously, and starting evenly it does not present the spotted appearance of many fields, and (5th,) the grain is much less apt to lodge. I have had, and also frequently seen, drilled oats stand well side by side with badly lodged hand sown grain where no other difference could be assigned than the mode of sowing. I allow the ground to dry sufficiently to bear rolling after plowing, then drill in the grain not more than two inches deep, one inch indeed on my heaviest lands, and then finish with the roller again. Large breadths of oats are well put in by sowing immediately on the fresh plowed lands, harrowing twice, first lengthwise of the furrows, then across, and finishing off by rolling the surface; the last an important matter in laying down a field of this grain. Should the soil be liable to have water stand upon it after a rain, it should be underdrained, or at least, after sowing, water furrows should be opened with plow and shovel for its exit; no grain but rice can be expected to become aquatic in its habits, to accommodate careless farmers. The amount of seed sown varies from two and a half to four bushels per acre, my own heaviest crops have been from three and a half bushels of seed. As a general rule the better and the heavier the soil the more seed it will bear; three bushels is the average and is safe. The earliest sown crop, except in very rare instances, is the best, both in weight and yield, though the eye may not detect the difference.

VARIETIES.

With respect to the kind to be sown there is much difference of opinion, but it seems well established that the *Black Poland Oat*, is one of the best, if not the best variety, weighing sometimes fifty pounds to the bushel. The *Imperial Oat*, is also very heavy, and is preferred in the Northern and Middle States to most other improved varieties. It has a clean bright, plump grain, almost equaling barley in solidity, and it is very prolific. The *White Poland Oat*, first distributed, I believe, through the *Agriculturist* Office, and now widely multiplied, is also a beautiful, prolific, and very heavy grain. The common *White Oats* are the most extensively cultivated in the United States, and are hardy, yielding tolerably well, varying with the season more than most others in weight, a bushel weighing from fifteen to thirty four pounds. Oats are found when long sown on the same farm to deteriorate both in the weight and yield, and great advantage results in obtaining seed from other localities, especially from cooler latitudes. I have twice imported Oats from England, the Potato Oat, and another variety of unknown name. When sowed they weighed 44 pounds to the bushel, but year after year they became lighter until they were abandoned for a black Oat obtained from Prince Edward's Island, N. B., which I have sown for a number of years without any perceptible diminution of weight or produce. Possibly under my present mode of selecting seed the English grain might have been kept up.

SELECTION OF SEED.

I adopt the following mode: taking a marketable article I place in the fan mill, instead of the usual screen, a board three or four inches shorter, and by a rapid turning blow over about one fourth of the grain. The portion which runs down its usual course will thus be the best and plumpest grain, and I find will keep the crop up to the standard weight apparently indefinitely, which is all we can expect in our latitude. I think farmers would find their account in this mode of obtaining most of their seeds. [This is certainly so—" like produces like."—ED.]

HARVESTING.

In harvesting, which is generally done by the reaping machine, care should be taken to guard against cutting too green, for although the straw is better for fodder, the grain, unlike wheat or rye, is not so heavy, as I have found from trial; and the injury from binding too hastily is greater, for the Oats pack more closely in the sheaf, shock, and mow. Owing to this close packing many farmers have abandoned the reaping machine, and returned to the cradle in harvesting Oats, the "gavels" thrown off the machine frequently receiving injury from wet, while the swath of the cradle will dry out after a shower, almost immediately, without even turning. It is the practice among some farmers to draw in their Oats without binding, the gavels being loaded on the wagon, with forks adapted thereto, in the manner of sheaves, buts outward, and then pitched indiscriminately into the mow like hay. If stacked, more care is used, the gavels being placed buts outward, at least on the outer course. But from repeated trials of both plans, I give the preference to binding; the difference in time is not noticeable, and the room required in the mow less; the thrashing, also, is much expedited. In the field they may be protected for some weeks, if necessary, by a mode of miniature stacking, as follows: I place from fifty to one hundred sheaves in a shock, commencing in the center, by laying four sheaves in the form of a cross, the heads together and over-lapping considerably, and in the angles others, for a center; then a ring with the buts out, the tops a little further in than the bands of the center sheaves, and build up to a point, capping with a large sheaf, buts upward and the tops spread evenly on all sides to shed the rain around the shock. It is well, however, to get all grain under cover as soon as practicable. [That is, as soon as there is no danger of heating in the mow.—ED.]

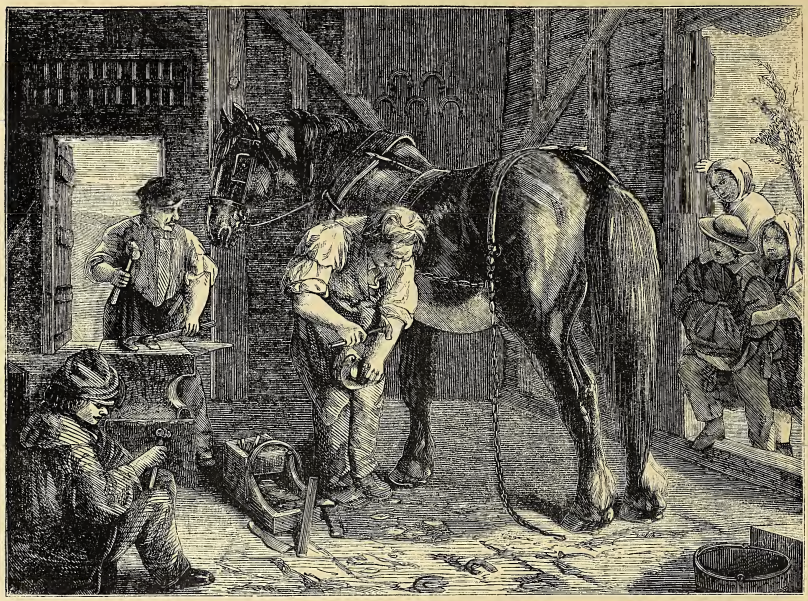
THRASHING AND MARKETING.

The thrashing is now almost entirely performed by horse power, machines being used and taking the place of the flail and of the old mode of treading out on the barn floor by horses. I find it most expeditious in cleaning up from the chaff to perform the operation twice; first with a large-meshed riddle or screen, and then with a finer one of say four meshes to the inch. A nice clean sample of grain is always of readier sale and will command a better price than the same article mixed with dirt and trash, buying grain being a science as well understood as selling it, and farmers can find little profit in paying freight and commissions on dirt in grain. The best market for Oats is probably New-York, if the producer is not so far off as to consume his profits in freights. The large grain dealers there, if applied to, will furnish bags to the grower at a small percentage, and sell the grain on moderate commission, often doing better for the farmer than he could for himself in that great Babel. There the Black Oat is preferred; in Philadelphia it is almost unknown, the white sorts taking its place.

GENERAL REMARKS, ROTATION, ETC.

On soils equally fertile, oats are uniformly heavier and more prolific in the cool latitudes and in moist seasons. They are esteemed, though I think unjustly, an exhaustive crop. Their place in the rotation in this latitude, is usually after corn; the Oat stubble is then plowed up for wheat, thus injudiciously, as it seems to me, bringing two straw crops close together. This course I have abandoned, and introduced clover between the two; sowing it thickly with the Oats, pasturing it the next summer, and plowing that sod up for wheat; the results are eminently satisfactory. [The rotation would then be (1,) corn on sward ground with manure; (2,) oats without manure, seeding down to clover; (3,) pasture; (4,) clover turned under and wheat sowed, seeding down to grass; (5,) wheat taken off and grass remaining; (6,7,8,) grass mowed two or three years—perhaps receiving top-dressing the second year—then wheat.—ED.] Oats are benefitted by almost any of the usual fertilizers. Lime applied immediately to the crop, has the effect of retarding its ripening, and is thereby often of questionable benefit, exposing the plant for a longer time to the accidents of the season, and also to insects. Ashes have rather the contrary effect, and seem to be peculiarly efficacious in increasing the yield. Nitrogenous manures, such as Peruvian guano, are apt to cause luxuriant growth and consequent lodging if applied too freely. The best mode of manuring the Oat crop, is through the preceding crop, getting the land in good heart, and not by specially stimulating the growing plant. On sod they rarely do as well as the quality of the soil would lead one to expect. The chief enemies of the Oat are: rust, the army worm, and the aphis. The army worm, if he comes, has it all his own way, though a deep furrow plowed round the field, the furrow slice thrown towards the fence, and pits dug at intervals, into which the worms fall, has proved measurably successful, many bucketsful of worms having been thus taken by single farmers. The aphis is a plant louse of a reddish color, that attacks the upper part of the stalk and the stems of the head, and sucks the juices, causing shriveling of the kernel, though the husk seems of full size. Very extensive damage was done to the crop by this insect during the past Summer. Rust has been extensively damaging in some seasons, particularly in the West. I believe no remedy is known. The above is the result of 15 years experience in farming, during the last 10 of which, Oat growing has been rather a specialty.

* The name and address of this writer (whose letter is post-marked New-Jersey) can not be found; will he please notify us that he may receive his prize.—ED.



THE VILLAGE BLACKSMITH.... FROM A PAINTING BY R. ELMORE, R. A.

Engraved for the American Agriculturist.

Man with the rugged sinews, man with the face of soot!
Come forge for us a horseshoe, fit for Eclipse's foot!

The principal figure in the beautiful picture which our artist furnishes for this number of the *Agriculturist*, is a very important personage to those who have horses to be shod. "No foot, no horse!" is a good old proverb, and the preservation of good feet, or the improvement of bad ones, largely depends upon the skill and care of the Village Blacksmith. Those who cluster round his forge these raw nights, to gossip over the latest news of the war, may not think it, but the part the Blacksmith operates upon is a complex and cunning structure, admirably adapted for its work, but liable to derangement and disease if neglected or improperly treated. As sure as the sparks fly upward, your horse, though he be worth five hundred dollars now, shall be lame, if he is long shod by an incompetent or careless Village Blacksmith. The latter is sometimes ignorant of the principles which should guide him, and too often despises their application when informed of them. He will rasp and pare and hammer as if the foot were a mass of insensible horn, whereas it is a complicated elastic spring, with a cushion attached, to receive easily the weight of the horse. If this were not so, fancy the shock which every stroke of Mr. Bonner's marvellous fast trotting mares must give to the joints of the frame above. Instead of preserving this elasticity with the greatest care, the workmanship of our Village Blacksmith is too often calculated to impair and destroy it. Hence inflammation of the interior tissues, navicular disease, and the incurable lameness consequent upon it. If you do not know about the navicular bone, the *hinge* which holds the coffin and coronet bones together, we have not space here to describe its functions. See to it that your Village Blacksmith does not bind your horse's heels to the rigid iron shoe so that they cannot expand when his weight comes upon the foot; for if he does, a contracted hoof and navicular lameness will follow. Sometimes there is hereditary predisposition to this. The stock of American Star need care in this matter. The famous English mare Cobweb inherited it from her sire, and though her own feet were very fine, she communicated it to her great son, Bay Middleton. He was a magnificent cripple at six years old, though he had been sold for $25,000. All the veterinary skill of England could not save him from incurable lameness.

The Village Blacksmith commonly has an ideal as to what shape a horse's foot should be, and he will twist and rasp the hoof to conform to it, if you will let him. Do not permit it, for the foot shod should be like the foot unshod, minus the iron which is to protect, not wrench and cramp it. They say that the devices of mantua-makers cause consumption and dyspepsia among fine ladies, and the Village Blacksmith will sometimes be guilty of corns, of pumiced sole, or of navicular arthritis, if not watched. He must be induced to regard his business as a progressive science, not as a mechanical operation which can not be improved. Insist upon it that he give the crust of the hoof at the heels a fair bearing upon the shoe. Limit him to five nails in the fore shoes, and seven behind, those on the inside to be well forward towards the toe. He will predict the loss of much iron, but regard him not. These nails are sufficient to keep the shoe on, and the inside quarter of the hoof being free, the heels expand naturally when the foot comes down in work. Our stalwart friend of the leather apron, too, may want to pare down the frog. Stop him! for if you do not, you will find, too late, that his knife has entered into your soul. This frog is the cushion, nature's own buffer and fender, between the foot and the solid ground. Then, hearing you speak in favor of open heels, some Village Blacksmiths will cut away the sides of the bars. This will make the heels *look* open, but it is just like the application of cosmetics to the skin. Temporary looks are obtained at the expense of permanent injury. Forbid peremptorily the burning of your horse's foot with a red hot shoe to make it fit. It will render the hoof hard and brittle, liable to sand cracks, and so will too many nail holes. The shoe moderately hot may be held to the sole to mark the places to be pared—the knife must do the rest. Usually the Village Blacksmith is a man of worth and probity, and though a little opinionated sometimes, address on your part will induce him to follow the instructions of science, and take more care in the shoeing of your horse.

For the American Agriculturist.

Hints on Cabbage Growing.

A failure of this crop is common from the disease called "anbury," or "fingers and toes;" the roots swell, and after a time rot off; new roots are often sent out which keep the plant alive, and give hopes of success. But the disease soon reaches the new roots, and after a hard struggle the plant dies, or starts too late to make a good head. Fortunately, this most destructive disease generally shows itself by the time plants are large enough to set, and where the roots show the least tendency to swelling, the plants should be rejected at once. The grand remedy of the cabbage growers who supply our large vegetable markets is, never to plant the same piece of ground with this crop two years in succession. The cabbage is more sensitive than most other plants, to feeding upon its own decay. For this reason, unusual care should be taken in preparing hot-beds for starting plants, during this month. If the same soil have been used for starting plants the year before, it will be very likely to impart the disease to the young plants. Very much depends upon the preparation of the seed bed, whether it be under glass or not. For late plants it is well enough to plant the seed in the hills, but for the early crop, it is indispensable to have either cold-frame plants, kept through the Winter, or those started as early as March, in a gentle hot-bed. Whatever the amount of manure used, there should be at least six inches of fresh soil upon the top. Leaf mold from the woods, mixed with sand or with yellow loam, makes a good seed bed in which to start the plants. The writer has always succeeded better with cabbage upon green sward broken up the previous Fall, than upon any other ground. In such a soil, we may use almost any quantity of stable manure with decided advantage to the plants. Hog manure is always to be avoided. I have never yet succeeded in composting it with so much muck as to make it entirely safe for this crop. Ashes are excellent, both as a manure and as a safeguard against insects. They should be used in the seed bed, and around the plants, soon after transplanting. JONATHAN.

A Dish of Green Peas.

This is one of the earliest garden crops that can be put into the ground. For the first crop, select the dryest and warmest corner of the garden, sheltered by a wall or a high and tight fence if possible, and open full to the south. The ground should not be manured the same year it is planted to peas, or the vines will grow too rampant, and bear few pods. It should, however, have been enriched the previous year. Some of the old school will tell you not to sow peas in the "new of the moon," lest the vines all run to stalks, and not to fruit. But let the moon alone, and sow the peas as soon as the season opens. The frost being well out of the ground, break it up by spading, and rake it down level and fine. With a garden line, lay off the drills as long as you like, and at least two inches deep. A good method is to make two drills six inches apart, then to leave a space two and a half feet wide, or more, for tall growing kinds, for a walk between them; then the next pair of drills, and so on. The peas are scattered in the drills about an inch apart, and then covered with the back of a rake. One row of brush is stuck for two rows of vines. For this purpose, the best material is brush from the woods, especially the fine bushy limbs of birch trees. Yet the spray of almost any tree will answer; and the bushes should be from three to six feet high, according to the kind of pea. Another method, often practiced where brush is scarce, is to drive in stout wooden stakes, six feet apart, along each row, then pass a line of strong twine from end to end of the rows, taking a turn around each stake as you proceed. Begin when the vines are about six inches high; put on a second line when they are two feet high; the tall varieties will want a third string. Do not put down the brush at the time of sowing. Let the plants get several inches high, give them two or three hoeings and thorough weedings meanwhile, the last time drawing up the soil around the stems to prevent them from being blown about by the winds: then bush them. To get a very early crop, sow the peas under the lea of a sunny wall, in drills running east and west, and have a frame of boards, shaped like an eaves-trough, to set over each row in frosty nights and during cold rains. Set it up on the edge by day to reflect the light and heat of the sun on the young plants. Of the many varieties now in market, we can not speak at length. *Early Kent* and *Daniel O'Rourke* seem, just now, to dispute the field as to *earliness*. Both of them and the *Prince Albert* are early, and fair quality peas. For a little later crop, the *Champion of England* ranks high: it is very sweet, rich and high flavored. The *Marrowfats*, of course, will always be in vogue.

A Spring Tart—Rhubarb.

Does anybody doubt, or not know the desirableness of this vegetable? Then we pity him. It is one of the finest things in the world, to make a pie or Spring tart. Apples often give out in April and May, and those which remain are wilted and tasteless. Man's stomach longs for something fresh, crisp and juicy: the pie-plant affords that very thing. It forms a connecting link in the year-long chain of articles for pie-making. Think, too, of the doctors' testimony that it is "one of the most wholesome, cooling and delicious substances that can be used for the table. For dysentery in children, it is an infallible remedy, stewed, seasoned with sugar, and eaten in any quantity with bread." We have tasted samples of fair wine made from this plant. It is also used for jellies and jams.

Mode of Culture.—Procure a few crowns, with roots attached, and set out only one in a place. Rhubarb will live in any kind of soil, but to get large, succulent stalks, the soil must be deep and rich. Five or six plants are enough for an ordinary family. Lay off a bed twenty feet long by four wide. Remove the top soil, break up and manure the subsoil heavily, and then return the top spit to its place. This last should be enriched with a light dressing of old manure, and if the land is a stiff clay a little sand should be worked in. Now set out the crowns by a line, four feet asunder, leaving the plump, pinkish buds an inch or two below the surface. This work may be done in the Fall, or early in Spring. New roots will soon form, and the growth will rejoice the eyes of the planter.

The after culture is very simple. Keep the ground free from weeds. Pluck no leaves the first year. In the Fall, put a peck or more of coarse manure around each plant. This will protect the roots, and furnish nutriment for the next year's growth. In the second Summer, the leaves may be plucked in moderation, and after that, quite freely. Let the plants, however, have their autumnal dressing, to be forked into the soil the following Spring. In our own grounds, we have pursued this course several years; and now the stalks and leaves of our plants are so magnificent, we are often asked the names of our new and improved varieties. We uniformly reply by simply pointing to the manure-heap.

Forcing.—If any one wants to get a very early tart or pie, let him (say, by the middle of this month,) set a barrel or rough box, headless and bottomless, over the crowns of several early plants, and surround the same with fresh manure from the horse stable. Put a few forkfuls inside of the barrel, and a bushel or more outside. This will soon generate a local climate of 50° or 60°, and give the plants a start while those out of doors are asleep. The barrels should be kept nearly or quite covered for ten days, and then gradually opened as the season and the plants progress. Add a little fresh manure outside, after the first week. As soon as the out-door plants are fit to cut, the forced ones should be uncovered and allowed to rest.

Varieties.—Good cultivation will improve the commonest varieties, yet there is a choice in sorts. Here are some of the best now known:

Myatt's Linnæus.—This, probably the cap-sheaf, has the least acidity of any known sort, and therefore is very desirable in these times, when sugar is so costly. It is very tender, needs no peeling when cooked; is also highly aromatic.

Myatt's Victoria.—Early, not very sour, productive, color dark red.

Tobolsk.—Stalks small, but of fine flavor, very early, good for forcing.

Giant.—Stalks round, green, very large, often four feet long, and as thick as a man's wrist.

Downing's Colossal.—Truly magnificent. Stalks very long and large, tender, high-flavored.

(PRIZE ARTICLE.)

Family Vegetable Garden.

BY P. C. REYNOLDS, ESSEX CO., N. J.

The garden is a *domestic institution* that has been too much neglected in this country, greatly to the detriment of the health and enjoyment of our people.

THE GARDEN SPOT should have a gentle descent toward the south, most writers say southeast, but there are grave objections to an easterly exposure. If after a very cold night in Winter the first rays of the morning sun fall directly upon the frozen plants, they are liable to be injured by the sudden thawing, while if more gradually thawed by the air before the rays of the sun strike them, they may escape. So in Spring, tender vegetables might survive a slight frost if not exposed to the direct rays of the morning sun. A garden should be protected from the northerly winds by hills or woods, or in the absence of these by a high, tight board fence or wall, and thus situated and protected will be several days earlier.

SOIL.—The best soil for a garden is a sandy loam, having but just enough sand to prevent its packing down hard, or baking after heavy rains, free from stones large enough to hinder the cultivation of the most tender plants, and containing enough vegetable mold to give it a dark color, as such a soil absorbs the heat of the sun more than a light colored one, and is warmer. Depth of soil is requisite to successful gardening, especially to the production of good root crops. The subsoil should be porous enough to permit the water to pass through it readily, but not so open as to allow the fertility of the surface-soil to leach through it. A subsoil of coarse sand or gravel would be liable to leach, while a porous loam, containing clay, would allow the passage of water, but retain the pabulum of plants. If the subsoil of a garden is so compact as to retain the water which falls upon it until it is evaporated, it will be a cold, sour garden spot. To ascertain whether it is too compact or not, take a shovel, (not

spade) and if you can dig a post-hole three feet deep without difficulty, it will answer, otherwise it should be subsoiled or trenched. The former method is the more expeditious for a large pit, the latter the more effectual.

SUBSOILING AND TRENCHING.—Subsoiling is performed by following in the surface furrow with a subsoiler, which merely raises the subsoil two or three inches, thus loosening without inverting it. It acts upon the subsoil somewhat as the mole does upon the surface. The furrow should be turned deep and *narrow*, so that the subsoiler—which is quite narrow—can break it all up. A garden should be made friable to the depth of at least two feet. But the gardener who means to do up his work thoroughly, even though it require a little more labor and expense at first, will trench his ground.

Trenching may be performed as follows: take a good strong spade, draw your line upon one side of your ground, and open a trench two spades wide, throwing out the entire *soil*, then press your spade its full length into the subsoil, raise the dirt a little, and let it fall back into its bed. Open another trench the same width, throwing the top soil on to the first trench. Loosen the subsoil as before, and so proceed until the ground is all trenched. To fill the last trench, take up the soil thrown out of the first in a wagon or wheelbarrow, and move it around to fill the last. An active hand would soon trench a large garden in this way, and it would not be necessary to repeat the operation in several years. A great deal of subsequent labor will be saved, and much more satisfactory results attained, by the proper preparation, and fertilization of the garden plot.

MANURING.—I would prepare my garden plot in the Fall, and after subsoiling or trenching the ground, would draw on well rotted barn-yard manure—a mixture of the dung of all the domestic animals—at the rate of about twenty five two-horse loads to the acre, and plow it in to the depth of about six inches. I would then draw on about half as much more, spread it over the surface, allowing it to remain upon the top until Spring, when I would turn it in and thoroughly mix all the manure with the soil by several plowings. If the soil had been much exhausted, I would apply fifty two-horse loads to the acre. The garden should receive a moderate dressing of manure every Fall. [Certain parts of the garden we prefer not to have manured every year.—ED.]

IMPLEMENTS.—The first thing needed to properly lay out the garden, walks, beds, and rows, is the *Reel and Line*. The reel should be of iron, and the line of hemp, at least six rods in length, and ⅛ of an inch in diameter. A spade and a shovel will be required in many of the operations, and to still further pulverize the soil for beds, and to add more manure to special crops, no implement is superior to the *digging fork*. To draw drills for sowing seeds at uniform distances, and in straight lines, some two or three *drill markers* are convenient. One should have the teeth about 11 inches apart, another should have them 15 inches; by taking out the alternate teeth it would answer to make drills 30 inches apart. Another should have the teeth 18 inches apart, so as to make drills of 18 inches and three feet distance. Each marker should contain about five teeth, and should be made of hard wood. The steel-tooth rake is very necessary to finely pulverize and level the surface of beds, and free them of stones, lumps, and rubbish. A *hand roller* is useful to smooth and compact the surface after the seeds are sown. One should be of hard wood or cast iron, and may often be used to advantage in crushing the lumps before sowing. The *garden trowel* is used in transplanting, where it is desirable to remove a lump of earth with the roots. A good *steel hoe* of the very best material and make, and the *Dutch* or *Shuffle-hoe*, are indispensable articles in the garden. The latter will greatly facilitate the labor of cutting up weeds between the rows. The *garden watering-pot* should be of the best tin, strongly made, and capable of holding twelve to fourteen quarts. The *rose* or *sprinkler* should be perforated full of very fine holes, so as not to beat down weak plants. A *wheelbarrow* with a wide wheel, and side-boards that may be very readily removed, is an important accessory of the garden. [We like the common, cheap railroad barrow very much, and besides would add to these necessary implements the *weeding fork* which becomes indispensable to whoever once uses it.—ED.]

THE HOT-BED.—To raise early vegetables, it is necessary to bring forward some varieties in a hot-bed. The aim is to afford artificial heat to plants before the ground is thawed or warmed up in the Spring. This is done by the fermentation of manure beneath them, while they receive the light and heat of the sun, the cold being excluded by the frame and glass. Dig a pit running east and west, 18 inches deep, 5 feet wide, and 12 feet long. Make a frame of inch-and-a-half stuff, spruce or pine, to fit within the pit, and about 2 feet above the ground on the north or rear side, and one foot in the front, and make all tight by battening. The sash should be of clear pine, 6 feet in length, and wide enough to contain three rows of 7 by 9 glass. The sides, ends, and middle pieces of the sash should be strong enough to prevent springing apart in the middle and thus allowing the lights to drop out. The glass should lap about ¼ inch, and be well puttied. The bed should be started about the first of March. Use horse manure, pretty full of litter, and slightly fermented. Fork it over several times, to break up the lumps, and mix the coarser and finer manure well together. Make the bed regular and level, beating it down with the back of the fork, leaving the manure about 20 inches deep. Put on the glass and wait two or three days until the manure has commenced heating, then spread the loam evenly over the surface, 4 or 5 inches deep. It should have been procured the Fall previous, sifted through a fine sieve, 13 holes to the inch—9 to the square inch.—ED.] and covered with straw so as to be ready for use before the ground is thawed. After putting on the loam, wait until it is warmed through before sowing the seeds. Nail narrow strips of boards on the inside of the front and back, just above the loam, to support a plank to sustain the gardener while sowing and weeding. The hot-bed needs close attention until the plants are all transplanted into the open grounds. In cold freezing weather it will need covering with mats or straw; in warm sunny days it will want airing; at all times it will require frequent waterings with tepid water. Always water at the close of the day, otherwise too much of the water will evaporate.

Cabbage, cauliflower, egg-plants, lettuce, peppers, and tomatoes may be sown quite thickly in the rows, which should be 3 inches apart; when the plants are 2 inches in hight, they should be thinned to 3 inches in the row. To forward tomatoes to be transplanted, cut sods 6 inches square and 4 inches thick, and place them in the pit, in an inverted position directly upon the manure. Set a small stick in the center of each sod to guide you in transplanting, and sow upon each sod about a dozen seeds, but not within an inch of the edge. Spread fine loam evenly over the seeds about ¾ of an inch in thickness, and press it down gently. After the plants have put out their first *rough* leaves, thin to four in a sod, keep well watered, and transplant when cold weather is past—say middle of May in latitude of New-York City. Too great heat, like the crowding of the plants, has the tendency to draw up the plants and make them spindling and weak; hence always have good ventilation when it is warm.

LAYING OUT THE GARDEN.—If the garden is to be for vegetables *exclusively*—with another plot devoted to fruits—I would leave a border about four feet wide around the outside of the fence, and inside of this I would have a good broad, permanent walk, and another broad walk running lengthwise through the middle of the garden. I would lay off the portion to be devoted to beds in plots about two rods wide—a convenient length for the rows—and divide them by narrow, temporary paths. In making walks, do not sink them below the surface of the beds, as they would be disagreeable promenades after a rain, but rather raise them in the center. Select a plot in the warmest part of the garden for those perennial plants that are not to be disturbed yearly by the plow—such as asparagus, rhubarb, etc., etc. Biennial plants will also find a genial place in the sheltered border.

ASPARAGUS.—The *Giant* is the standard sort. Sow the seed very early in Spring, in drills 1½ inches deep, and 15 inches apart; cover and roll. When well started thin to 3 inches apart. Run the shuffle-hoe frequently between the rows, and weed by hand often. In soil prepared and manured as previously directed, the roots will be large enough to transplant when one year old. Early in the Spring, measure off 24 feet in one of the 2 rod wide plots, and dig a trench of manure, and about 9 pounds of salt. Lay it off in four beds, four feet wide, separated by paths two feet in width. Mark out with your line two rows in each bed, leaving two feet between the rows, and cut trenches six inches deep, one spade wide. Carefully take up the roots, set them in the trenches 15 inches apart, and cover them so that the crowns shall be 4 inches below the surface of the beds. Keep the bed free from weeds, and early in November cut down the stems, rake them off, and cover the beds about 3 inches deep with stable manure. In the following Spring dig in the manure as deep as you can without disturbing the roots, and repeat the operations of the previous year. As the asparagus comes up this third season, cut a portion of the larger and more tender stalks for the table, when they are from 6 to 10 inches high. In the latitude of New-York City asparagus can be enjoyed from about the 20th of April until the middle of June. Market gardeners cut off the stalks three or four inches below the earth, but the blanched part is rejected in eating.

BEANS.—*Dwarf or Snap.*—Desirable standard varieties are: Early Valentine, Yellow Six Weeks, Mohawk, Royal Dwarf, or White Kidney, and Early Marrowfat. About the 20th of April, sow the first three in the list, and about every two weeks thereafter until middle of June. The last two may be sown from first to middle of June for Fall and Winter use. Plant in drills two inches deep and 18 inches apart. To keep down the weeds use the shuffle-hoe freely, and draw a little dirt around the plants once or twice with the common hoe.

POLE OR RUNNING BEANS.—The desirable sorts are: Large White Lima, Dutch Case Knife, White Cranberry, Scarlet Runners. Plant in hills three feet apart both ways, set poles about 8 feet long firmly in the ground, plant from 4 to 6 beans in a hill early in May and cover about two inches deep. When the vines have run about six feet high, pinch off the ends to promote ripening of beans. Keep soil mellow and clean, draw a little dirt around the plants two or three times during the season.

BEETS.—Desirable sorts are: for the table, Extra Early Turnip (or Early Bassano.) Early Blood Turnip, Long Blood. They require a deep, rich soil. Sow in drills nine inch deep, rows eighteen inches apart, and thin out to six inches. Stir the soil frequently, and occasionally pretty deep. Sow the turnip-rooted varieties as early as possible, and the long blood for Fall and Winter use, the latter part of Spring. They may be preserved through the Winter packed in barrels or boxes with dry sand or soil.

BROCCOLI.—The standard sorts are: Early White, Early Purple, Early Walcheren, Early Purple Cape, of which the last is the most desirable. Sow first of April, in shallow drills eleven inches apart. Transplant in June and July, two feet each way. Cultivate like cabbages and commence using in October. BRUSSELS SPROUTS.—Treat every way like the foregoing. Not good until touched by frost, after which they make good greens.

CABBAGE.—Desirable sorts are: Early York, Winningstadt, Large Early York, Early Ox Heart, Early Dutch, Large Flat Dutch, Green Globe Savoy, and Red Dutch for pickling. If very early cabbages are desired, the Early York may be sown *early in September* in drills three inches apart, rows six feet long. Keep them weeded clean, and just before the ground freezes up, thin them to three inches apart in the row, and surround the bed with a frame six inches high in front and about fifteen inches in the rear so as to carry off the water. Cover over with boards, and in mild weather remove the boards in the middle of the day to air the plants. In very cold weather cover with straw, (or straw mats) being careful to remove the covering as it moderates. So soon as all danger of *hard freezing* is over, transplant into the open ground in rows eighteen inches both ways. They may also be much forwarded by sowing in hot-beds early in March. Keep up a pretty high temperature, water lightly, but often: air in the middle of sunny days. They will be ready to plant out soon after the middle of April, and fit for the table by the latter end of June, some two to three weeks later than those wintered over. Sow the later sorts the latter part of April, in a rich bed, rows eleven inches apart, and thin to three inches. Keep them clean; stir the soil with shuffle-hoe, and there should be strong plants before the middle of June. Select the larger ones to transplant first, and the smaller ones will come in for the Winter supply. Transplant in rows, two and a half feet each way, and stir the ground about once a week until the cabbages head. Do not hill up around the cabbage, but keep the ground level and stir often, and they will not be much affected by severest drouths. A few hours before commencing operations, thoroughly saturate the seed-bed with water, so that the ground is soaked as deep as the roots extend. The plants may each be taken up with a garden trowel, and a ball of earth three inches across the top, removed with them. If set in holes corresponding, and the earth pressed firmly around the balls, the plants will not be much checked by the removal. Where practicable, a cloudy day should be selected for transplanting. When it is not convenient to remove a ball of earth with the plants, they should be "dibbled" in with the *finger*, and the soil pressed close around the roots.

WINTERING CABBAGE.—A few may be kept in the house-cellar, but the better way is to build a light cellar under the barn, or carriage-house for storing the greater share of the vegetables, whether for family use, or stock feeding. In the absence of a barn cellar, a permanent out-door pit may be cheaply constructed by digging a pit in a dry place, twenty feet long, three wide, and two deep. Throw the dirt a little back from the edge, set posts about eight feet long, two feet in the ground, in the middle of each end, and also in the center of the pit. Lay a good stiff ridge pole on the top of the posts, and pin it fast. Take slabs long enough to reach from edge of pit to ridge pole and make a roof. Cover the slabs with about six inches of dirt digging a trench around the outside, and beating the earth roof smooth and hard with back of shovel so that it will shed rain. Make a door in each end of the pit to ventilate it in mild weather. Pull up your cabbages and store them in, heads down, two layers deep. You can stow away two hundred large cabbages in a pit of the above dimensions, and take them out whenever desired. In the very coldest weather a few bundles of straw set against the

doors may be necessary to keep out the frost. For Spring use, dig a trench in a dry place, one foot wide, and as many feet in length as you wish to bury cabbages. Lay a couple of rails, or poles along the bottom, place in the cabbage, heads down, and cover with dirt, stems and all. They come out when the ground thaws, fresh and green.

CARROTS.—Desirable kinds: Early Horn, Long Orange, Altringham, Long White. [The first two are best for the table.—ED.] Sow Early Horn, first of April for early crop, and latter part of July for late crop. For main crop, sow in May of the other sorts, in rows eleven inches apart. Thin to three or four inches in the row and keep a close lookout for weeds. Just before the ground freezes, take a sharp spade or hoe and cut off the tops half an inch above the crowns, and dig with spading fork. Preserve a few for winter use, as a recommended for beets, and bury the rest in pits. They are excellent food for horses and milch cows.

CAULIFLOWERS.—Desirable sorts: Large Early London, Large Late London—the former for early use, the latter for late crop. Thorburn's Nonpareil is a good early sort, quite inclined to head, and "Lenormands" is of the same description. The culture is the same as cabbage, taking a little more pains, and you will be repaid with a more delicate luxury. They do not head as certainly as cabbage, but frequent hoeings will promote healing.

CELERY.—The standard sorts are: Early White Solid, Giant White Solid, Red Solid. Sow early in Spring in a rich seed bed. Water frequently and protect from frosts. Thin out plants to three inches. The latter part of July dig trenches one foot deep, and same in width, put in the bottom about three inches of cow or hog manure. Mix it well with soil, and set your plants nine inches apart in the trenches. When the plants are six inches high commence to earth up so as to blanch them. Be careful not to get the dirt into the centers of the plants. Continue to earth up at intervals of two or three weeks, and when the celery has completed its growth, draw up the earth almost to the top of the plants. It may be preserved for Winter use by standing in a box with layers of dry soil between.

CORN (SWEET).—Desirable sorts are: Darling's Early Sugar, Excelsior Sugar, Burr's New Sugar, Stowell's Evergreen. Plant early in May, in rich, mellow soil, three feet each way, stir the ground frequently, and make broad flat hills. (Plant once or twice in May and then about once a week until the fourth of July, to have a succession till frost comes.—ED.)

CUCUMBERS.—Good varieties: Early Short Green, Early White Spine, Green Cluster, and Long Green. For open culture plant early in May in hills four feet each way, slightly elevated. Look out in the early morning for the striped bug, and large squash bug, killing all you find, or you may lose your crop. When they have well the start of the bugs, thin out to four plants in a hill. If they are inclined to run together, pinch off ends of vines. When the cucumbers are of suitable size for use, take them from the vines, leaving none to ripen, as they will continue in bearing longer by such a course. A later planting may be made for pickles.

EGG PLANT.—The varieties are: Long Purple, Large Purple, White and Scarlet Chinese. The first two for use. Sow early in the hot-bed, and when the weather is warm transplant into rows two feet apart, one foot in the row. [In warm soils and locations they will generally fruit, if sown early in the open ground, but earlier started plants are best. ED.]

LETTUCE.—Desirable kinds are: Early Curled Silesian, Ice Drumhead, Butter, Brown Dutch, Victoria Cabbage, White Cos [and Large Indian.—ED.]. For earliest, sow in hot-bed early in March, Curled Silesian, or Butter; transplant early in April into rows eleven inches apart, four inches in rows. For succession, sow in open ground once a month. Frequent hoeings will promote a rapid growth upon which depends its tenderness and goodness.

MELONS.—*Musk Melons.*—The desirable sorts are: Fine Nutmeg, Green Citron and Jenny Lind; the latter is earliest, the former two best. About the middle of May lay out the hills four feet each way; with a shovel take out one foot square of soil six inches deep; with a digging fork dig in some horse manure; draw on the soil again so as to elevate the hill some two inches above the level, sow at least a dozen seeds to a hill, and when they have put forth their rough leaves, thin to four plants. To repel striped bug, mix guano and plaster in equal quantities, dust the foliage of the vines while the dew is on with the mixture, and as it becomes washed off and the bugs return, repeat the operation.

WATER MELONS.—The Early Mountain Sprout, Black Spanish, Ice Cream and Orange are all good varieties, ripening about in the order of the list. Give about the same culture as for musk melons, only put the hills six feet apart each way. They like a light sandy soil enriched by manure.

NASTURTIUMS.—There are large and dwarf varieties, the latter more for ornament than for use. Sow in latter part of May or early June, in drills 2½ feet apart, cover an inch deep; thin to eight inches. The tall kind must have brush, poles, rough stone walls, or something else to run on.

OKRA.—Improved Dwarf Green, Long Green. Plant in latter part of May, in drills three feet apart, and thin to one foot. The pods are used for soups while green and tender, or sliced and dried for Winter use. [This makes a most excellent, rich soup, and should be more generally cultivated. ED.]

ONIONS.—Desirable sorts: Large Red, Yellow Dutch, White Portugal, Potato, and Top Onions. The ground should be rich, and free as possible from weeds. Sow early in Spring in drills eleven inches apart. [Several years on the same ground.—ED.] Cover half an inch, and roll down well. Keep down weeds by frequent use of the shuffle-hoe, and hand weeding. For early use, I prefer the Potato Onion to all others. Plant in September, or early Spring, in rows fifteen inches apart, 8 inches in the row. They will be ripe early in July.

PARSNEPS.—Varieties: Guernsey or Cup, Long White. [Add Hollow crowned as best for the table.—ED.] When the ground is fully warm, sow in drills fifteen inches apart, cover lightly, and thin to three inches apart. Before the ground freezes, take up what are desired for Winter use and pack in a box with dry dirt. The rest will keep well in the ground until Spring.

PEAS.—Desirable sorts are: Princesse, Dan'l O'Rourke,* Tom Thumb, Warwick,* Prolific or Strawberry, Champion of England,* Blue Imperial, White Marrowfat.* (Those with a star require bushing.) It is considered quite a desideratum to get green peas as early as possible. Princesse and Daniel O'Rourke are the earliest. Prolific or Strawberry is but little behind them. Sow those which do not require bushing, in rows three feet apart; cover two-and-a-half inches deep. The others want to be four feet. Witch Hazel makes a good durable bushing, and should be trimmed up fan-shaped. Peas should be sown as early as possible on a light, dry soil. A little poudrette strown in the drill will hasten their growth. When up, loosen the earth on either side of the row with the shuffle-hoe. When a little larger, draw a little dirt to the row, and stir the soil frequently until they are in bloom.

PEPPERS.—Best varieties: Cherry, Large Squash, Long Cayenne, Large Bell. [Bull nose and Sweet Mountain.] Sow in hot-bed early in April, or in open ground a month later. Transplant latter part of May 18 inches each way.

POTATOES.—Desirable sorts: Early Sovereign, Dykeman, Mercer, Peach Blow. Potatoes should be planted in April, to ripen before the heavy Fall rains which increase the chances of rot on rich land. A dry sandy loam, if rich enough, is the best for potatoes. A teaspoonful of ashes on the hill just as they appear above ground is beneficial on most soils. Plant in hills three feet each way and four inches below the level. Stir the surface two or three times, and just before the vines fall over, hoe them for the last time, making low, broad, flat hills. When the tubers are grown enough to crack open when boiled, they will do to commence upon. When the vines are fully dead, dig them with the spading fork, and store them in a dry, cool, dark room, until there is danger of freezing, then remove to a frost proof cellar.

SWEET POTATOES.—Lay the smaller tubers on the manure in a moderate hot-bed, middle of April. Mark out rows three feet apart, scatter horse manure along the marks, cover about six inches with dirt, and early in June break off the sprouts from the tubers and set them out one foot apart.

PUMPKINS.—Standard sorts are: Large Cheese, Connecticut Field, Cashaw. If planted in the garden, they should not be in the vicinity of squashes, melons, or cucumbers, or they will mix. Plant in hills eight feet each way, and cultivate as Melons.

RADISHES.—The best varieties are: Early Frame, Early Long Scarlet, Short Top, Early Scarlet Turnip, Long White Naples, White Turnip, Black Spanish, White Spanish. The first three are desirable for early use, the next two for Summer, and the last two for winter use. Sow as early as possible in Spring on light sandy soil, warmed up by manure, and for a succession once in two weeks through the season.

RHUBARB.—Varieties: Linnæus, Prince Albert, Victoria. Sow in drills, fifteen inches, one inch deep. Transplant in Fall or early Spring three feet each way. Cover lightly with fine manure every Fall. Rhubarb can be forwarded very much in Spring by placing a headless barrel over the hill, and surrounding it with warm manure two feet high. In cutting for use, always leave several stalks in each hill to maintain the vigor of the root. Seed stalks should be cut out as soon as they appear.

SALSAFY OR OYSTER PLANT.—Sow in drills eleven inches apart, half an inch deep, and thin to four inches. Cultivate like the parsnep. Leave in the ground over Winter.

SPINACH.—Varieties: Round Leaved, and Prickly for Winter. For early Spring use, sow in August and Sep tember. Scatter a little straw over the leaves and be tween rows, on approach of Winter. Sow early in Spring for Summer use, in drills fifteen inches apart, half an inch deep, and thin to six inches. When the outer leaves are two or three inches broad, gather for use, leaving the inner ones to continue their growth.

SQUASHES.—The best varieties are: Early Golden Bush, Early Green Striped Bush, Early White Scallop Bush, Summer Crookneck, for Summer; and for Winter, the Hubbard, Winter Crookneck, Boston Marrow, and Folk. The White Leghorn, Mammoth Cuba, and Honolulu, are new and promising, especially the latter. Plant early in May, the bush varieties four feet each way, the others six feet, and cultivate same as cucumbers. Use the Summer kinds before the skin becomes hard.

TOMATOES.—Desirable sorts: Large Smooth Red, Large Yellow, Red Cherry, Yellow Cherry—the latter two for pickling. The Fejee Island Tomato is newly introduced—a large, round, solid tomato, of a pale red color, a little late, and I think, slightly deficient in flavor. It is a great object to grow tomatoes as early as possible, so as to prolong their season. Sow in a warm hot-bed about the middle of March, in rows three inches apart, and thin to three inches in a row. If the plants are inclined to grow too spindling, give them plenty of air. If likely to get too high before the weather will admit of setting them out, transplant them in the same bed. When danger of frost or cold winds is passed, prepare the ground moderately rich, mark out the rows four feet each way. Transplant with care, removing a ball of earth with the roots, and set the plants two inches deeper than they stood in hot-bed. A few plants should be kept in reserve to supply the places of such as may fail, or be destroyed. They should receive frequent hoeings each time, drawing a little dirt around them, forming a broad hill. As the fruit begins to set, pinch off the ends of leading branches so as to hasten the maturing of fruit. Repeat this operation often, or the fruit will become too much shaded. Tomatoes managed as above, will ripen in the latitude of New-York, before the middle of July, on ordinary soils. As they are seldom destroyed by frost before the first of October, the season may extend more than two and-a-half months. Then, if taken when most plenty, and put up in glass bottles from which the air is excluded, they may be enjoyed the year round.

TURNIPS.—Desirable kinds for the table are: Early Dutch, and Red Top Strap Leaf, for early; Yellow Aberdeen, and Rutabaga for late Winter and Spring. For early use, sow as early as possible in Spring. For later, sow Rutabagas in July, and Yellow Aberdeen in August. The rutabagas should be in drills two feet apart, and covered half an inch, the others fifteen inches apart. Slight frosts will not materially injure them, but they should not be exposed to hard freezing.

I believe that I have now enumerated many of the most valuable varieties of vegetables that it is desirable to cultivate in an ordinary Family Vegetable Garden. The gardener should be ever vigilant; should not allow the weeds to get the start of him, nor the insects to destroy his tender vines and plants before he is aware of it. He should do all of his work in a neat, and systematic manner, have his rows and paths straight, and his curves true and regular, and then he will delight to view his garden himself, and have others to visit it. He should keep his tools carefully housed when not in use, and have them cleaned after using, so that they may remain bright and last longer. The very best implements are always cheapest in the end, although the first cost may be greater.

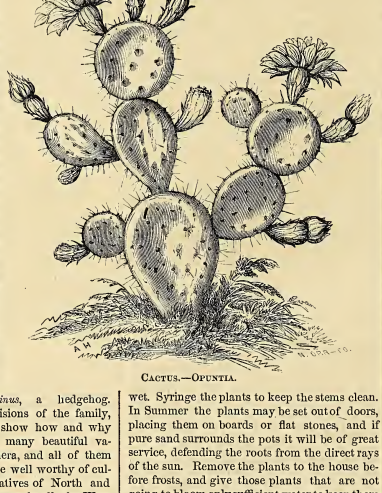
GARDEN SEEDS FOR AN ORDINARY FAMILY.

4 oz. Asparagus.	4. oz. Watermelons.
4 qts. Beans, in variety.	½ oz. Okra.
8 oz. Beets, in variety.	2. oz. Onions.
¼ oz. Broccoli.	2 bus. Potato Onions.
¼ oz. Brussels Sprouts.	1 oz. Parsneps.
½ oz. Cauliflower.	1 oz. Peppers.
4 oz. Cabbage, in variety.	8 qts. Peas, in variety.
1 oz. Carrots.	1 oz. Pumpkin.
½ oz. Celery.	8 oz. Radish.
2 qts. Sugar Corn, in variety.	½ oz. Salsafy.
2 oz. Cucumbers.	2 oz. Squash.
½ oz. Egg Plant.	8 oz. Spinach.
1 oz. Lettuce, in variety.	2 oz. Tomatoes.
2 oz. Muskmelons.	2 oz. Turnips, in variety

All kinds of seed should be sown quite thickly, as quite a proportion of the best often prove poor, and another portion will be destroyed by insects, while if too many are spared, it will be very easy to pull up the excess.

The Cactus—Good for the House.

This family of succulent plants is remarkable for tenacity of life—so great in some varieties that they retain vitality for years in a hot, dry atmosphere without receiving a particle of moisture except that absorbed from the atmosphere. This tenacity of life is owing to their peculiar structure, which allows them to exhale moisture but very slowly, for they have no proper leaves. We know of no other tribe of plants so peculiarly adapted to growing in rooms, or which repays so abundantly the little care required in the culture. It is to be regretted that so little attention is paid to this beautiful and interesting class of plants, because they are so easily cultivated and are not impatient of occasional neglect. The species and varieties are very numerous, amounting in all to several hundreds. The cactus family is divided into several genera, such as the *Opuntia* (of the general form and growth of which our engraving gives a good representation,) *Mammillaria*, called the ball cactus, having spines clustered around a small tubercle; *Cereus*, having for the most part long pliant shoots; *Epiphyllum* with stems resembling leaves; *Melocactus* resembling melons; *Rhipsalis*, most of the species having flexible stems, like (*rhips*) willow twigs; *Echinocactus* named on account of the prevailing form, from *echinus*, a hedgehog. There are still other divisions of the family, but these are sufficient to show how and why it is divided. There are many beautiful varieties in each of these genera, and all of them are so curious that they are well worthy of cultivation. The cacti are natives of North and South America, as well as nearly all the West India Islands. They are mostly very impatient of frost, the least freezing generally destroying them. There are, however, a few hardy species, of which one of the most common is found very plentifully among the highlands along the Hudson River, and Long Island Sound. It is commonly called the Prickly Pear, and belongs to the genus *Opuntia*. Its flowers are yellow, like most others of this class. Though the cactus will grow in nearly pure sand, it does best on good soil. A good compost is equal parts of rich loam, decomposed cow manure, and white sand. Mix these well together and keep in a dry place, always ready for use. The main points are to allow a period of growth and a period of rest, according as nearly as possible with the nature and habits of the plants. When growing water well, and but little when at rest. For all practical purposes the cacti may be divided into two classes—Winter blooming and Summer blooming. Of course the time of flowering may be somewhat varied by culture, but it is best to follow the natural tendency of the plant. Those who can had better purchase their plants while in bloom, unless they are acquainted with the varieties. As soon as the plants have done flowering take them out of the pots and crumble off half an inch or so of the soil all around the ball adhering to the roots; then put them into pots about one inch larger than those from which they were taken, putting in plenty of pieces of broken bricks or pots in the bottom for drainage. Give them a little water, just enough to settle the soil around the roots and water them not more than once a week thereafter. Place them in a warm situation where they will receive plenty of light and when the plants begin to grow, water them twice a week, or often enough to keep the soil moist but not



CACTUS.—OPUNTIA.

wet. Syringe the plants to keep the stems clean. In Summer the plants may be set out of doors, placing them on boards or flat stones, and if pure sand surrounds the pots it will be of great service, defending the roots from the direct rays of the sun. Remove the plants to the house before frosts, and give those plants that are not going to bloom only sufficient water to keep them from shriveling. Those that show signs of blooming (a reddish tint seen around their buds) should have a regular supply of water. The necessary temperature of the room is from 60° to 75°, or it may be even warmer, but make no sudden transitions from heat to cold, or the buds will blight. The wants and habits of the plant will be readily learned by observation.

When cuttings are taken off they should be placed on a shelf in a dry place and left there for one or two weeks before potting them; this causes them to loose part of their watery substance and they root more readily. Put them in soil composed of at least half sand, and give them but very little water until they are rooted.

A Hint to Pear Growers.

Theories and rules are all very well, in their time and place. But just now, we have a *fact* or two for young pear-cultivators. Having noticed that a certain plain and quiet man, year after year brought very handsome pears to the County Exhibition, while many others brought poor fruit or none, we resolved to visit him and see how this thing was done. On asking to see his pear-trees, he smiled, and said he couldn't make much of a show. He led us to a square patch of ground adjoining his vegetable garden, where were just twenty-five trees, all of them on the quince-stock. A few things were visible at a glance. *First*, the wood was healthy and vigorous; the bark was clear of insects, and the foliage a bright green. *Second*, the trees had been well trained from the start. The lower branches shot out at about eighteen inches from the ground, and they were the largest and strongest of all. The other tiers of branches tapered gradually to a point at the top, the whole tree forming a pyramid, like a handsome fir-tree.

Very well, so far. But what means this flooring of straw spread all over the ground? "That's my summer mulch, sir; my soil is rather sandy, and is apt to suffer from drouth in mid-summer; so I cover it with this light, porous blanket. This straw is bright and clean, so it don't bring in vermin nor seeds of weeds; and then, it is so light and open, it does not prevent free circulation of air and moisture about the roots of the trees. I got this idea from Mr. Charles Downing, who is the father of many good ideas."

On a little closer examination, we found that the straw was laid about six inches thick over the entire fruit-garden, paths and all. Our friend said he spread it on in the month of June, just after the ground had received its Spring dressing and cleaning. When once down, it saved the labor of any further hoeing until the middle of September, when it was removed to allow the young wood plenty of time to ripen up hard and bright before Winter. If left on through the Winter, it was quite sure to harbor mice. Just before cold weather set in, our friend was in the habit of winding a thin straw band around the trunks of his trees. He thought this would prevent sudden thawing of the bark after hard freezing. In Autumn, he gave each tree half a bushel of half-rotted manure, spreading it as far as the limbs extended over the ground.

The foregoing was the whole of his secret method of raising regular and handsome crops of pears on the quince stock. The labor of putting down the straw and gathering it up, was much less, he assured us, than the cultivation of the ground would be, if not mulched.

What Grapes shall I Plant?

This is the question which just now occupies the thoughts of fruit-culturists perhaps more than any other. It comes to us from the North and South, the East and West. We can not put it by, if we would; so here is our reply: But our answer, to be intelligent and useful, must depend altogether upon the circumstances of the inquirer, where he lives, and whether he wants to raise grapes for the table, or for wine.

1. If one lives north of latitude 43°, and wishes to dabble in wine-making, we fear he will not make a very marketable article. Southern France, and even southern Ohio will excel him. But the best grapes to try with, are the *Delaware* and *Clinton*. And then, for the dessert, leave out the *Clinton*, and add the following: *Hartford Prolific*, *Concord*, and *Logan*. If one does not live north of lat. 43°, he may, in some seasons, ripen the *Diana* and *Rebecca*, provided he gives them a warm exposure. With the *Isabella* and *Catawba*, it would be useless to meddle. For a select list of four under this head, we would say, plant *Delaware*, *Concord*, *Hartford Prolific*, and *Logan*.

2. If living south of lat. 43°, and above 40°,

the two sorts first named above must still be the wine-grapes. In certain favored localities in this district, the *Catawba* ripens sufficiently well to make a fair sort of wine, but the Summers are hardly long enough to give the clusters all the saccharine and other accompanying elements, needful to make a fair article. Sweetness may be added, it is true, by putting in sugar, but this destroys the purity and delicacy of the flavor, and leaves us only a pleasant (?) kind of cordial. The *Delaware* and *Clinton* ripen well throughout this belt of country, and make very fair wines. For the table, the assortment of grapes is quite extensive, affording, beside those already named, such as the following: *To Kalon, Union Village, Cuyahoga, Allen's Hybrid*, and perhaps others. For a select list of four, we would name: *Delaware, Rebecca, Diana, Isabella.*

3. South of the above, the range of selection widens. There, the *Catawba* yet rules supreme as the leading wine grape; though many of the western vinters are beginning to introduce the *Delaware*, and think that in time it will almost supersede the *Catawba*. A select list of six for the table would include the following: *Delaware, Catawba, Rebecca, Diana, Isabella* and *To Kalon.* For some, the *Concord* would be put in this list, on account of its large, showy clusters, its earliness and hardiness, but it is *second* in *quality.*

4. In addition to the foregoing, if any one wishes to experiment with some of the newer kinds which promise well, we would advise him to plant the *Crevelling, Roger's Hybrid No.* 15, the *Adirondac*, and the *Woodward.* There are other new seedlings soon to be brought out, of which we shall know and speak more at a future time.

The Man and his House in Keeping.

The principle of suggestion has a very wide range. A man's dress and his house are apt to be in keeping with himself; the furniture is, or should be, in keeping with the house, and the garden, grounds, etc., in harmony with the dwelling.

Happening to express some ideas like the above in a mixed company, lately, a little dapper, pinched up man who overheard, began to banter us, and said rather smartly, "Pray sir, what sort of a house do *I* suggest? what sort, ha?" Eyeing him a moment, we said, "You suggest a little, narrow, pinched up, Gothic cottage, made of very thin clapboards, and painted in a very spruce manner." He turned away. "And what sort of a building do you put down for me?" inquired a square, plain, commonsense man. "You suggest a plain, solid, unpretending house, with a white fence all around it, and a row of maple trees in front."

Probably the reader now gets one idea, and we beg him to dwell upon it a little. Whenever a man builds a house, let him not look around and inquire about 'Squire Jones' Grecian mansion with its Corinthian pillars, or Judge Brown's English villa, or Dr. Smith's French chateau. Rather, let him sit down and consider, first, what his own wants and comforts require in a house; and secondly, how much he can allow for ornament, and what will be in keeping with his character, position, and tastes. His house should express himself, should be a sort of natural outgrowth and flower of his mind and character and means, so much so, that people will say, as they pass by: "Well, that's just like him; it's natural—in keeping with the man." And let this appear in the man's furniture, books, dress, and the ordinary surroundings of his dwelling. His trees and fences and walks should show it. Aye, they *will* show the man, whether he will or no.—Who will build us a model farm-house, one which happily expresses the true idea of life in the country and on the farm? Not smart and showy and uncomfortably fine. Not covered with gimcracks, or built in imitation of some fashionable city house. Rather, let it be plain, solid, roomy, with the idea of repose and comfort written all over it, and penetrating it through and through. Give it an air of dignity, earnestness, sincerity, and open-handed hospitality. Give it, above all, a home-like look. Of course, the appendages of barns, woodhouse, sheds, etc., should be in keeping with the main building. The grounds should be ample, neat but not overnice, and the trees for shade should be few and massive, not over-crowded. We see, now and then, some approaches to this sort of building, but the complete expression of our idea is yet to be made. Let our readers look into the vein we have struck; it is worth working out further.

Home Ornaments—Skeletonizing Plants.

This beautiful art is now brought to such extraordinary perfection, as to give one almost an impression of a new creation, not of art but of nature; and it is indeed nature. Our commonest leafy forms, stripped of the green tissue which constitutes their principal substance, are preserved as delicate white skeletons, retaining perfectly the form of the leaf, with its most intricate, reticulated net-work of veins and fibers, and may be grouped or arranged in bouquets according to the dictates of taste or fancy. Thus it not only furnishes amusement and beautiful ornaments, but it is also very instructive to those who take an interest in the hidden beauties of the vegetable kingdom. When a leaf has been reduced to a skeleton, its net-work of nerves and veins is spread out before us, and we are enabled to study the various ramifications of its vascular system. Nature pointed out the way, but man was slow to follow in this instance, as he is in many others, for doubtless the ancients must have observed leaves that had fallen in damp places, and thereby had their cuticle destroyed, leaving only the skeleton. Yet it appears that they were not artificially prepared until 1645, when Marcus Aurelius Severinus published a figure with a description of the skeleton of a leaf of the *Cactus opuntia.* (See preceeding page.) Although Severinus brought this art prominently before the scientific world, we find no mention of it again until it was revived by Ruysch in 1723. This naturalist first prepared the leaves by employing insects to eat away their pulpy parts just as we often see our rose leaves eaten, but he found that the insects did not always stop when they had eaten out the pulp, but often destroyed the solid parts that he wished to preserve, so he had to discard these anatomists and employ a process similar to the one described on page 117, vol. 19, of the *American Agriculturist.* (See also page 70 of this paper.)—Du Hamel prepared the fruit of the pear in the same manner, illustrations of which were given in the Transactions of the Academy of Science of France in 1730.—Francis Nicholls went still further, for after he had reduced the leaf to a skeleton, he split it in halves, dividing every fiber. The specimens of this art on our exhibition table, from Mr. W. F. Heins, we think will excel anything of the kind that has been produced in years past, for in these he not only skeletonized the leaves, but nearly the whole plant, after which they were bleached to snowy whiteness. They are worth seeing.

Cheap Washes for Buildings, Fences, etc.

Take a large tub, or a common barrel, and slack one bushel of good fresh lime, covering the lime with boiling water. After letting it stand three or four hours, pour on cold water enough to make it as thin as ordinary white-wash. Then take one pound of white vitriol and one quart of fine salt, dissolve them, and pour into the lime water. If a *cream color* is wanted, stir in half a pound of yellow ochre. If a *fawn* color, add to half pound of yellow ochre, a quarter pound of Indian red. If a neat *gray stone* color is desired, take half a pound of French blue, and a quarter pound of Indian red. For a neat *drab*, add half a pound of burnt sienna, and a quarter pound of Venetian red. Other colors can be made to suit one's taste. Every body who has half an eye, (or weak eyes!) sees that either of the above colors is preferable to the glaring *white* which has so long been used on fences and out-buildings. The white vitriol, we may add, seems to harden and fix the color, so that it is not necessary to repeat the white-washing for several years. *

Coffee for the Times.

The present high price of coffee will lead to its less abundant use (not a bad result), and also impel many to adopt some substitute as a "warm drink." Here are two or three suggestions taken at random from the *Agriculturist* "Drawer:" A "Constant Reader," writes: "To 1 lb. of the best unburned coffee, add 3 lbs. of cleaned rye, previously washed, scalded and dried. Burn the whole carefully, and grind fine as wanted for use." The rye will add "body" to the fluid, and afford quite as much nourishment as an equal weight of coffee grains. 2.—The Editor of the Miner's Journal says he has for sometime used a beverage made of a quarter of a pound of coffee, and two quarts of wheat combined. "The wheat is boiled about twenty minutes in water, and then placed in a pan and browned the same as coffee. So far, we prefer it to the genuine article, and it certainly is more healthy. With a pound of coffee and eight quarts of wheat, which costs from 3 to 4 cents a quart, this beverage is produced so cheap that it makes up all the difference in the advance in price, of both tea and coffee."

3. Miss L. E. Palmer, of Luzerne Co., Pa., suggests a return to the old fashioned crust coffee, which has long been used, and is still used in many families as a "warm drink."—It is what the physicians call bread or crust "panada." Miss P. directs as follows: "Brown some stale crusts, or bits of bread, as thoroughly as possible without burning. Place in the coffee pot and pour boiling water over them; they require very little boiling. A coffee cupful of crusts will make two quarts of fluid."

Bouilli, or Pot-au-Feu.—A French National Dish.

The inquiry in onr last has called forth responds from several correspondents who will please accept our thanks. They are somewhat alike, and we have only room for the following—just as written:

1. A condensed translation made for the *Agriculturist* by Mrs. Elizabeth Bagg, from a work by a noted Freuch Chemist (Raspail), entitled "Manuel Annuaire de la Santc," (Annual Manual of Health,) under thc chapter headed "Cuisine Hygienique," or hygieue of the Kitchen: "Choose meat of the best quality that can be procnred, whether beef or mutton. Place your meat in twice its bulk of water, add a handful of salt, and let it boil very gently, removing all the scum. Theu add an onion stuck with three or four cloves, a handful of celery and chervil, three cloves of garlic, a pinch of pepper, a laurel leaf, and a burnt onion, with a very few carrots and turnips. Keep up a gentle ebullition for 3 or 4 honrs. Such a *bouilli* will alone suffice to cure indigestion. To be eaten with toasted bread, or better still, boiled rice or vermicelli, and other Italian pastes."

2. Contributed by S. L. Urmston, Beaver Grove, Ill.: "Take a brown earthen crock—a kettle will answer. Put in 6 lbs. of beef, and 4 quarts of water, sct near the fire, and skim. When nearly boiling, add 1½ spoonfuls of salt, ½ lb. of liver, 2 carrots, 4 turnips, 8 young or 2 old leeks, 1 head of celery, 2 onions, and 1 burnt onion, with a clove in each, and a piece of parsnep. Skim again, and let it simmer 4 or 5 hours, adding a little cold water now and then. Take off part of the fat, put slices of bread into the soup dish; lay half the vegetables over and half the broth, and serve the meat separate with the vegetables aronnd."

3. From a subscriber at Germantown, Pa.: "Two or three pounds of beef from neck or breast, after being well washed, put it in a pot twice the size of the meat, and fill up with cold water; let it simmer at least an hour, skimming all the time. Then add 2 large spoonfuls of salt, 1 large onion in which you will stick 4 cloves, a bunch of greeu onions, celery, chervil, a little garlic, a leaf of the bay laurel tree, 1 large or 2 small carrots, 2 or 3 turnips, a little parsley. A small teaspoonful of brown sugar gives a nice taste and a pretty color to the soup. Let it simmer for 5 honrs; then put in what you please—bread cut up in blocks which you put in just before sending to the table, or boil in the broth tapioca, vermicelli, macaroni or dumplings made quite small. No pepper until on the table.——The above recipe was given by a *Parisienne*, but American cooks can adapt it to American palates." [All the above would need some "*adaptation*" to suit onr taste.—From N. M. Root of Hillsborough Co., N. H., we received a recipe, the same as No. 2, which is accredited to Soyer.—ED.]

To Cook a Beef's Heart.

We stated in the February *Agriculturist*, (page 37) that owing to want of knowledge of the value of beeves' hearts, or of the method of cooking them, the N. Y. City butchers find slow sale for hearts weighing 6 lbs. each, at 10 cents a piece. Several correspondents from the country write that they consider this part of the animal quite a delicacy. The following are some of the directions sent to the *Agriculturist:*

1. "H." of Genesee Co., Mich., says it is excellent cooked thus: "Gash it, and fill it with stuffing, the same as a turkey; then boil it in water enough to cook it, so that when done there will be just enough to form a gravy."

2. J Langdon, Vinton Co., O., recommends (for stuffing we suppose) ¼ lb. beef suet, 1 lb. bread, 3 eggs, a little parsley, nutmeg, pepper, and salt.

3. L. E. Kimberly, Litchfield Co., Conn., writes: "Take the heart and skirts, soak over night in cold water. Boil until tender; when cold, chop all together very fine, and sprinkle in a little salt. When wanted for use, take what will be sufficient for a meal, put it in a frying pan over a slow fire and season with butter, pepper, salt and sage. A little flour and water is thought an improvement by some, as the heart itself is very dry."

4. T. B., near Moorestown, N. J., writes: "Make a good dressing of wheat-bread, pepper, salt, and a little piece of butter; wet it with cream, or milk, (if you have neither cream nor milk, a little water will do); fill the heart with it; skewer it well; put it in a pot with plenty of water, and stew it down so as to make a good gravy. It makes a good and cheap meal; my family think it as good as any part of the beef."

5. S. S. Barstow, of Sullivan Co., N. H., gives the following simple directions: "Boil the heart tender. Then chop, but not as fine as for mince meat; add a little boiling water, a piece of butter, salt, pepper, enough wheat bread crumbs to thicken it a little, and simmer all together. Very palatable."

Note.—A friend at our elbow says a beef's heart is the very best of meat for mince pies. If so, it is strange that our city pie-men have not found it out ere this.—ED.] [Dog-meat is cheaper.—*Printer.*]

Well Tried Recipes for Good Things—but not very Cheap.

Coffee Ice Cream.—Brown 2 gills of coffee; put it hot and nnground into a qnart of sweet rich milk, boil it, adding the yolks of 8 eggs, strain it through a sieve, sweeten and freeze it, giving frequent and thorough agitation. If properly done it will not be discolored.

Light Cake for Breakfast or Tea.—One cup of sugar, 2 eggs, ½ cup of melted butter, 1½ cupfuls milk, 2 teaspoonfuls cream of tartar mixed with the flonr, 1 teaspoonful of soda, flour enough to make a stiff batter. It will bake in 20 minutes if the oven is hot.

Coffee Cake.—One cupful of butter, 1 cupful of sugar, 1 cupful of molasses, 1 cupful of liquid coffee, 1 teaspoonful of soda, 2 teaspoonfuls cream of tartar, flour enough to stiffen it, cloves, cinnamon and nutmeg to taste—add fruit if you please.

Windsor Cake.—Two cupfuls Indian meal, 4 cupfuls flour, 4 cupfuls milk, ½ cupful molasses, 1 teaspoonful of soda, bake in pound cake tins. Half the quantity may be used.

Two Ways of using cold boiled Fish.—(1) Take 2 lbs of cold fish, cut it into very small pieces, scald 1 pint of milk in a sauce pan, mix in enough flour to make a paste, and ½ lb. butter; season with pepper and salt, and then whip in the yolks of 4 eggs, one by one; butter a dish, lay in first a layer of fish, then of the paste, and so on to fill the dish. Bake ¾ hour in moderate oven.

(2) Cut up a fish in convenient pieces, and put in a jar a layer of fish and then spices, (pepper, cloves, allspice and mace to taste,) until the jar is filled; then put in vinegar euough to cover thoroughly. Tie a paper tightly over the jar; then spread a paste of flour and water over the paper, set it in the oven for 8 hours. Blue fish is good, but shad is better. If rightly done, the bones will be entirely absorbed. It is excellent.

Crullers.—Dissolve 1 teaspoonful of saleratus in 4 spoonfuls of milk, or in 3 of milk and 1 of wine; strain it on a tumblerful of flour, adding 4 spoonfuls of melted lard or butter, and a teaspoonful of salt; beat 4 eggs with 7 spoonfuls of rolled sugar; work all together with a grated nutmeg, and add flour to make it roll out easily. Cut out and fry as usual in plenty of hot lard.

Savoy Cake.—Half lb. of fine sugar, ¼ lb. of flour, 4 eggs, half the grated rind and juice of a lemon. Beat the whites of the eggs to a froth, add the sugar gradually; when the oven is ready, stir in the lemon and yolks well beaten; sift in the flour as light as possible; drop by half spoonful on buttered tins. Sift on a little white sugar and bake immediately.

Finale of the Corn Bread Exhibition—Balance of 100 Recipes.

Below we give forty more of the recipes or directions, accompanying the loaves of Corn Bread and Corn Cake, at the recent exhibition at the *Agriculturist* office, with the epitomized notes of the Committee. These will be fonnd not less interesting than those given in our previous two numbers. It is almost remarkable that in all of the hundred recipes published, no two appear to be exactly alike; and the same would be the case, should we give the 120 others which we have on hand. We would be glad to do this, but probably our lady readers generally, will find all they desire in those so far printed, and we can not spare any more room—at present at least. We therefore close the subject, with again returning our thanks to the public spirited ladies, who contributed the works of their fair hands to the enterprise, which, we humbly trust, will be the means of inciting a much greater interest in a subject of so mnch importance as that of promoting the more general use of our own native and abundant cereal crop.

In printing the "Prize Recipes" for Corn Bread, a typographical error occurred, and we reprint two here, in the exact words of the contributors.

34. (1st prize.)—Two quarts meal, one pint light bread sponge, half pint flour, tablespoonful of salt, and warm water sufficient to wet the whole; work well, and let it rise; then work over, put in the pan, let it rise again, bake one hour and a half in a brisk oven; this is good steamed or toasted, at a week old.—Mrs. Jane J. O'Brien, Carrick, Alleghany Co., Pa."

24. (2d prize.)—Mix 2 quarts of new corn meal with 3 pints of warm water; add 1 *teaspoonful* of salt, 2 teaspoonfuls sugar, 1 large *tablespoonful* hop yeast. Let it stand in a warm place 5 hours to rise; then add ¾ pint, or 1½ cupfuls of wheat flour, ½ pint warm water; let it rise again 1½ hours; have a pan well greased with sweet lard, into which pour it, and let it rise a few minutes, then bake in a moderately hot oven 1 hour and 20 minutes. This is much better hot.—Mrs. Lott Cornelius, Locust Valley, Queens Co., L. I." [The chief error in printing this at first was in recommending a tablespoonful of salt, instead of a teaspoonful, a rather important error, to be made by two bits of type-metal.—ED.]

No. 2. Corn Bread with Cost.—By Mrs. Louis C. d'Homergue, Middlesex Co., N. J. One lb. corn meal, 2 c.; 1 lb. wheat flour, 3½ c.; 1 pint rising or yeast, ½ c.; 1 tablespoonful salt, ¼ c.—total 6¼ cts.; scald the meal in 1 quart boiling water, let it get lukewarm; put in rising, knead in the flour; add salt, let it rise; bake 1 hour in moderate oven. (*Com. Notes:* "Cheap; good.")

No. 5. Corn Bread.—By Mrs. H. C. Compton, Essex Co., N. J. One quart corn meal, 1 quart buttermilk, 1 teaspoonful soda, 2 eggs; bake 30 minutes. (*Com. Notes:* "Light, well baked, very white, good.")

No. 14. Molasses Corn Cake.—By Mrs. J. H. Anner, Rockland Co., N. Y. Two cups corn meal, 1 cup wheat flour, 2 cups molasses, 1 cup sweet milk, 1 egg, 1 teaspoonful salt, 1 teaspoonful soda, 2 teaspoonfuls cream tartar, a lump of butter size of egg. Bake 2 hours. (*Com. Notes:* "Very light and good.")

No. 27. Corn Bread.—By Mrs. S. S. Jessup, Harlem, New-York Co., N. Y. Take 1 lb. corn meal; rub into it ½ teaspoonful salt, and 1 teaspoonful soda, 1 egg, and a tablespoonful of lard or drippings; mix with 1½ pints of sour milk; pour the mixture into a buttered pan, and bake ¾ hour. Cost a little less than 5 cents. (*Com. Notes:* "A very good loaf.") No. 28, a wheat and Indian loaf, by the same, was very excellent. Recipe lost, probably taken away by some admirer of the loaf.

No. 40. Corn Meal Bread.—By Mrs. Mary J. Davis, Kent Co., Md. Two gallons warm water, 2 gallons white corn meal, 3 quarts fine wheat bran, (sifted through a corn meal sieve from wheat bran,) 2 tablespoonfuls salt; mix well together; set in a warm place 6 hours in an earthen jar; then stir well again and bake. (*Com. Notes:* "A monster loaf, good quality, wholesome.")

No. 43. Corn Bread.—By Mrs. S. J. Piue, Suffolk Co., N. Y. One and a half pints Indian meal, ½ pint wheat flour, ½ pint good emptyings, and a little salt; add warm skim milk, sufficient to make a batter stiff enough for a spoon to stand in; raise 4 hours; bake ¾ hour in slow oven. (*Com. Notes:* "Well baked, light, very good."

No. 63. Corn Cake.—By Miss E. Merrit, Orange Co., N. Y. One pint sweet milk, 1 pint sour milk, 1 quart corn meal, 1 tablespoonful lard, 3 tablespoonfuls molasses, 1 teaspoonful soda, 1 teaspoonful salt; beat well together, and bake in a quick oven 1½ hours. (*Com. Notes:* "Well baked, and good.")

No. 64. Corn Bread.—By Miss E. Merrit, Orange Co., N. Y. One cup sweet milk, 1 cup sour milk, 4 tablespoonfuls cream, or 1 of butter, 2 tablespoonfuls Graham flour, (flour ground coarsely from good, well cleaned wheat, and not bolted,) 1 teaspoonful soda, 1 teaspoonful salt, Indian meal enough to make stiff batter. Bake 1 hour. (*Com. Notes:* "Light, well baked, a nice loaf.")

No. 68. Indian Loaf.—By Mrs. M. T. Willis, Queens Co., N. Y. One and a half quarts Indian meal, scalded with 1½ pints boiling water, and immediately thinned with 3 pints tepid water; add ⅔ quart unbolted Graham flour, ⅔ quart chopped sweet apples, 1 gill molasses, and 1 spoonful salt. Bake in a hot oven 6 or 8 hours. The apple may be omitted. (*Com. Notes:* "Very good for those who like a *moist* loaf.")

No. 76. Corn Bread.—By Mrs. D. G. Henry, Addison Co., Vt. Two quarts corn meal, 1 quart wheat middlings, 1 cupful molasses, 1 teaspoonful saleratus; mix with 1 pint buttermilk, and cold water enough to make it very soft; bake 4 hours with a moderate fire. Keeps well one week in cool weather. (*Com. Notes:* "A very large loaf. Quality fair. Not quite enough baked.")

No. 80. Corn Loaf.—By Mrs. Ermina Moody. (No address.) Five parts good corn meal, 1 part wheat flour; mix the flour and meal well together; then add 1 cent's worth yeast, ⅓ cup molasses, ½ teaspoonful salt, and warm water enough to make a stiff batter; set to rise in a warm place; when risen sufficiently. bake 2 hours in a moderate oven. I prefer rye to wheat flour. Cost 7¾ cents. (*Com. Notes:* "Well baked, quality good.")

No. 81. Corn Bread.—By Mrs. John Welles, Hartford Co., Conn. One part wheat flour, 5 parts white corn meal, 1 teaspoonful sugar, and one of salt for each loaf; stir well together; wet with warm milk to the consistency of thick batter; raise with common brewer's yeast, using twice the amount as for all flour; bake 1 hour, cool gradually. (*Com. Notes:* "Well baked, light, good.")

No. 82. Corn Cake.—By Mrs. N. Dean. New-York City. 3½ lbs. corn meal, 1 quart molasses, 3 pints boiling water, 1 tablespoonful salt. Mix the corn meal, salt and water; after a thorough stirring, add the molasses, stir again, and bake in a hot oven 2½ hours. (*Com. Notes:* "A large, fine looking loaf, but not quite light enough.")

No. 83. Corn Bread.—By Mrs. H. E. Moseley, Hampden Co., Mass. Two and a half pints corn meal, 1 pint boiling water to scald it, to be cooled after a few moments with ½ pint cold water. To this add 2 large spoonfuls good, lively yeast, 2 of molasses, and 1 teaspoonful fine salt. Mix well, and knead in ½ pint wheat flour. When sufficiently risen, bake 2 hours in a stove oven. (*Com. Notes:* "Well baked, fair quality.")

No. 85. Brown Bread.—By P. Jane Tibbetts, Litchfield Co., Conn. Two and a half pints corn meal, ½ pint wheat flour, 2 spoonfuls molasses, 1 cup sour milk, 1 teaspoonful saleratus; mix with sufficient cold water to make a thin batter; bake in a rather slow oven 5 hours, in a covered tin, the cover overlapping. (*Com. Notes:* "Properly baked. light, good.")

No. 86. Corn Meal Tea Cake.—By Mrs. Eliza Renoud, Fairfield Co., Conn. Two teacups buttermilk, 1 teaspoonful saleratus, 2⅓ cups corn meal, 1 cup molasses, 2 eggs, 2 cups flour, 1 teaspoonful ginger; bake ½ hour. (*Com. Notes:* "Light, well baked, quality fair.")

No. 87. Corn Bread.—By Mrs. Eliza Renoud, Fairfield Co., Conn. Two cups light yeast, made from flour, 1 cup milk and 1 of water, lump of saleratus, size of large pea; stir it up with meal, and let it rise; butter the pan; then stir again, and pour in: when light, bake 1 hour. (*Com. Notes:* "Light, well baked, of good quality.")

No. 88. Wheat and Indian Bread.—By S. B. H. Williams, New-London Co., Conn. Easily made, thus: scald 1 pint corn meal; make thin enough for griddle cakes; add enough cold water to make it lukewarm; then add 3 pints corn meal, and 3 of wheat flour; mix thoroughly about as stiff as common brown bread; bake, according to size of the loaf. 1 hour for this size, and longer for a larger loaf. The material for the loaf sent costs but 2 cents, the above mixture being sufficient for six such (*Com. Notes:* "Not quite light enough, but well tasting, made of good corn, probably freshly ground, which is half the battle.")

No. 89. Corn Bread.—By the same. Contains only 1 part of flour to 5 of corn meal. Made otherwise precisely as No. 88. The contributor says: "If still lighter bread is desired, a little molasses and soda can be added, but we prefer the natural sweet taste of the meal, if the bread is not quite as light." (These loaves, 88 and 89, were decided by the committee, to be not as light as desirable; but they had the pure, unadulterated, delicious taste of corn meal, undisguised by molasses and alkalies—just what unprejudiced tastes love. Who does not smack the lips with pleasure while munching boiled corn from the cob in August? Corn bread, almost as simple, more healthy, and about as finely flavored, can be made.—*Rep.*)

No. 104. Corn Loaf.—By Mrs. J. H. Fullerton, Yorkville, New-York Co., N. Y. Two cups water, blood warm, 2 tablespoonfuls molasses, 2 tablespoonfuls vinegar, 1 teaspoonful salt, 1 teaspoonful lard, ½ cup wheat flour, 1 teaspoonful soda in sufficient water to dissolve it; mix all well together; add 2½ cups corn meal. Bake 1 hour in a quick oven. This recipe makes excellent griddle cakes, with less meal to make a batter. (*Com. Notes:* "Well baked, light, fair.")

No. 106. Corn Meal Bread.—By F. L. Collins, Litchfield Co., Conn. Two lbs. sifted corn meal, 5 oz. wheat flour, stirred into the following ingredients: 1 quart sour milk, 2 teaspoonfuls saleratus, 2 eggs well beaten, 1 tablespoonful brown sugar, butter the size of an egg, 1 teaspoonful salt. The mixture to be about as stiff as for pound cake; bake in a medium heat 1¼ hours. (*Com. Notes:* "Not baked quite enough, otherwise good.")

No. 108. Indian Loaf.—By Mrs. Barnes, Kings Co., N. Y. Five cups corn meal, 1 cup rye flour, 6 cups boiling water, 2 tablespoonfuls molasses, a little salt. Scald the corn meal; let it stand until cool; then add the molasses, rye, and salt; let it stand over night; in the morning bake in a deep pan 3 hours. (*Com Notes:* "Light and good, but rather too much crust formed in baking.")

No. 109. Yellow Corn Bread.—By Mrs. Barnes, Kings Co., N. Y. One quart corn meal, 1 quart boiling water, and a little salt. Mix and bake in a shallow pan 1 to 2 hours. (*Com. Notes:* "Very economical, and pretty good.")

No. 111. Corn Cake.—By Mrs. Barnes, Kings Co., N. Y. Two cups corn meal, 2 cups milk, 2 eggs, 2 tablespoonfuls sugar, ¼ teaspoonful soda, and a little salt. Mix and bake in a shallow pan 1 hour. (*Com. Notes:* "A very good tea cake.")

No. 112. "Little Rhody."—By Mrs. J. E. Macomber, Newport Co., R. I. Two and three quarter lbs. corn meal, 1¼ lbs. rye flour, (being same price as corn meal, and less cost in proportion to the loaf, than if one-sixth of wheat had been used,) 1½ pints sweet milk, 1 quart boiling water. Pour the boiling water upon the corn meal, mixing both together; then put in the milk and rye meal, and mix all together. A moderate oven the first hour; then increase the heat, and let it remain in the oven 4 hours from the first. It is well to bake in the evening, and let it remain in the oven over night. Dish used, an iron kettle, covered. Weight of loaf, 6½ lbs. (*Com. Notes:* "A large, well looking loaf of good, substantial, healthy bread.")

No. 113. "Cousin Rhody."—By Mrs. J. E. Macomber, Newport Co., R. I. One quart boiling water, 2¼ lbs. corn meal, 1 lb. rye meal, 1 pint sweet milk. Mix the boiling water with the corn meal; add the rye meal and milk, mixing all together. Bake 4 hours in a deep tin pan covered. (*Com. Notes:* "A very nice loaf, had it been baked more.")

No. 114. Cheap Corn Meal Bread.—By Mrs. George S. Jacobs, Middlesex Co., Mass. Mix 1½ pints corn meal with 1 teacupful flour; add 2 tablespoonfuls molasses, 1 cupful sour milk, and enough saleratus to remove the acidity; next add sweet milk, if you have it, if not, cold water will answer; mix nearly as soft as you would for soft gingerbread, and add a little salt. Bake from ¾ hour to 1 hour. (*Com. Notes:* "Well baked, light, well tasted."

No. 115. Corn Cake.—By Mrs. Benj. F. Chase, Newport Co., R. I. One pint corn meal, ½ pint wheat flour, 1 pint milk, 3 eggs, 2 teaspoonfuls cream tartar, 1 cup sugar, 1 teaspoonful salt; bake ½ hour. (*Com. Notes:* "Very nice. For breakfast or tea, it would be hard to find anything better.")

No. 116. Corn Bread.—By Mrs. B. F. Chase, Newport Co., R. I. Five pints corn meal, 1 pint rye meal, 1 teacupful molasses, 2 teaspoonfuls salt, 3 pints milk, or water, or both, (enough to form a soft batter.) Put into a tin kettle, with a closely fitting cover, (a tin mould with a hollow, open center is better;) set in a kettle of hot water, and keep it boiling through the day; let it remain in the water over night, and you have a warm loaf for breakfast. (*Com. Notes:* "Good.")

No. 117. Corn Bread.—By Mrs. B. S. Arnold, Providence Co., R. I. One quart corn meal, 1 teacupful flour, 1 teacupful molasses, ½ cupful sugar, 1 teaspoonful saleratus, dissolved in a pint of sour milk, and 1 egg; mix to a stiff batter, and bake 1¾ hours. (*Com. Notes:* "Of fair quality.")

No. 132. Indian Bread.—By Mrs. Wm. Hinton, Kings Co., N. Y. 1¼ lbs. sifted Indian meal, ½ lb. wheat flour (rye will do as well,) 3 ounces lard, 1 gill home made yeast, 2 tablespoonfuls salt; mix the meal and flour; rub in the lard thoroughly; add the yeast and salt, and as much warm water as will make a soft dough; this to be done at bed time; in the morning put it into a pan rubbed with butter, and bake 1 hour. (*Com. Notes:* "Well baked, light, well tasted, but too much salt.")

No. 141. Cup Cake.—Mrs. A. D. Weymouth, Worcester Co., Mass. One quart corn meal, 1 teacupful flour, 1 quart sour milk, 1 tablespoonful molasses, 1½ teaspoonfuls saleratus, 1 teaspoonful salt. I take the milk first; add the meal without scalding; then add the other ingredients, raise thoroughly, and bake 1½ hours. Cost—corn meal 2½c., wheat flour ½c., sour milk 2c., molasses, saleratus, and salt, ½c.—total 5½c. Weight 4 lbs., or 1⅜c. per lb. (*Com. Notes:* "Light and good.")

No. 145. Corn Bread.—By Mrs. J. G. Caldwell, Queens Co., N. Y. Two quarts sifted corn meal; scald the meal, add cold water enough to leave it but milk warm; then add ½ teacupful yeast, a little salt, and ⅓ teacupful rye flour. Stir all together; let it stand over night; in the morning add ½ teacupful molasses, and 1 teaspoonful saleratus; put in a pan, and bake 2 hours. (*Com. Notes:* "Well baked, light, good.")

No. 153. Brown Loaf.—By Mrs. D. S. Wood ward, New-London Co., Conn. Two and a half quarts corn meal, mixed with scalding water until thoroughly wet; when nearly cool, add 1 quart of rye meal, 1 cup of yeast. ⅓ cup molasses; mix thoroughly, and set to rise 1 hour. Bake 3 hours. (*Com. Notes:* "A large, fine looking loaf, not quite well baked, but otherwise good.")

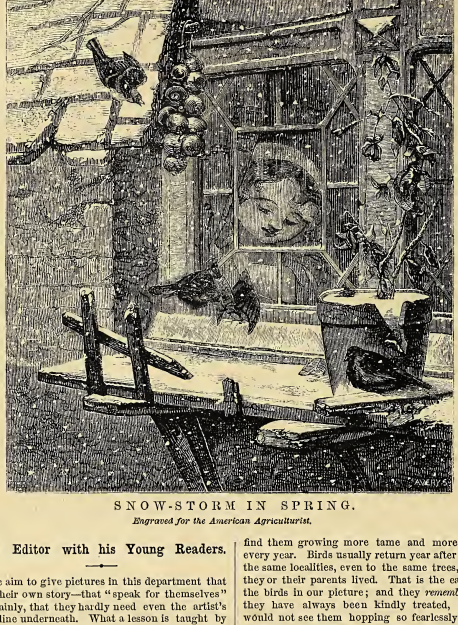
No. 159. Corn Sweet Cake.—By L. E. Palmer, Luzerne Co., Pa. One teacupful of butter and two of sugar, rubbed well together; 5 eggs, whites beaten apart, 1 cup sour milk, 3 cups Indian meal, 2 cups wheat flour, 1 teaspoonful saleratus, and half a nutmeg. Of course it would be better with a larger proportion of flour, but we think it pretty good, made as above. (*Com. Notes:* "Light, well baked, a very good cake.")

No. 187. Corn Bread.—By Arabella Culverwell, Laporte Co.. Ind. One pint sour milk, 1 pint corn meal, 2 tablespoonfuls wheat flour, 1 tablespoonful butter, 2 tablespoonfuls molasses, 1 teaspoonful soda, 1 of salt, 2 eggs. Bake 1 hour. (*Com. Notes:* "Pretty good.")

No. 188. Rye and Indian Bread.—By Mrs. H. Edwards, Allegany Co., N. Y. Three pints corn meal, 1 pint rye meal, sifted through a common sieve; mix with boiling skim milk enough to wet it thoroughly, and stir with a spoon until well mixed; let it stand 1½ to 2 hours, stirring often; add 1 teaspoonful salt; fill 2 iron basins with the dough, turn them together, and put them in the stove, and bake moderately 2 to 3 hours; then leave to cool gradually in the stove. (*Com. Notes:* "A large loaf of very fair quality, and specially economical.")

No. 189. Family Loaf.—By Clarissa Edwards, Allegany Co., N. Y. Two quarts skim milk, scalding hot, 1 tablespoonful salt, 1 quart corn meal, stirred in by handfuls, ⅔ pint rye meal, not bolted, but sifted; after stirring thoroughly, add 1 cup cold milk, stirring smartly; let it stand 10 or 15 minutes, then put into a cast iron basin, cover with another basin; bake not less than 4 hours, 6 is better; can hardly be baked too much, unless burnt. (*Com. Notes:* "A good, wholesome food.")

No. 193. Corn Bread.—By Mrs. D. W. C. George, Worcester Co., Mass. Five cups corn meal, 1 cup flour, ½ cup molasses. 1 teaspoonful saleratus, and 1 teaspoonful salt. Mix soft, and, if the weather is cold, let it stand mixed over night. To avoid hard crust, steam 2½ hours; then put in a moderate oven long enough to dry off and brown a little. (*Com. Notes:* "A fair loaf.")



SNOW-STORM IN SPRING.
Engraved for the American Agriculturist.

The Editor with his Young Readers.

We aim to give pictures in this department that tell their own story—that "speak for themselves" so plainly, that they hardly need even the artist's title line underneath. What a lesson is taught by the above picture. It is early Spring time. The birds have come forth from their Winter hiding places, but an untimely March snow storm has caught them, and has spread its mantle over the ground, and covered up the insects, and last year's seeds upon which they feed. See, with what confidence they come to the window, and say as plainly as they can say: "Please, Miss, throw us a few crumbs, for we are hungry." Did it ever occur to you, young friends, that nearly all birds are naturally *tame*; that they are not afraid of men and women, or of boys and girls, until they are taught by harsh usage to fear them? Travelers who have visited uninhabited Islands, tell us, that at first the birds come around them as familiarly, as they do around our oxen, cows, horses, and sheep, here. You never see the birds afraid of domestic animals. They will even light upon the backs of the sheep, and pick up the stray locks of wool to line their nests. They light down among the cows, and hop around between their feet. They would be just as familiar with us, if we never misused them. And would not that be pleasant? How many more nice apples, and cherries, and plums we should have, if no one had ever frightened away the birds, but if, on the contrary, these little songsters felt free to build their nests among our trees, and gather for themselves and their little ones the insects, which are their natural food. (Please turn to page 75, and read something there about the Birds and Insects.) It will take a long time to bring back the birds to their *natural* confidence in us, but it may be done. We ask all our young friends to try and bring this about. Never chase the birds, or halloo, or say "shoo" to them, and never permit the boys to throw sticks or stones at them, and you will soon find them growing more tame and more useful every year. Birds usually return year after year to the same localities, even to the same trees, where they or their parents lived. That is the case with the birds in our picture; and they *remember* that they have always been kindly treated, or you would not see them hopping so fearlessly to the well-known window to meet their old friend.

A Strong Man—How he Came So.

Thirteen years ago, a small nervous boy, 16 years old, entered the Freshman class of Harvard College, at Cambridge, Mass. So diminutive and puny was he, that only one out of about a hundred of the young men in the class measured and weighed less. He still weighs less than 150 pounds we believe, though about 29 years old. Yet at Brighton, Mass., on the 9th day of last October, this same man lifted and held up a platform on which stood *twelve* men, every one of them larger than himself. On the 21st day of November he lifted **2,007** lbs., equivalent to shouldering a very large horse, or ox, or lifting a whole load of hay, or thirty three bushels of wheat, or nearly *thirty six bushels of shelled corn!* This great weight of 2,007 lbs., was supported on his shoulders by means of a wooden yoke, like that used in the sugar grove to carry two pails of sap. He expects yet to lift **3,000** lbs., and we shall not be greatly surprised if he does so. We refer to Dr. Geo. B. Windship, of Boston, whom we take the liberty of naming the "American Sampson."—There appears to be nothing in his natural form, or constitution, different from other men, and there seems to be no reason why other men may not attain to the same strength. We would not, however, advise any one else to aim at his particular feats, but the method by which he has gained his present physical health and power, affords a useful lesson to boys, and girls too. Most of our young readers have heard of the man who carried an ox, and how he did it. He began by carrying a calf, and carried it daily until it grew up. In a similar manner Dr. Windship began to take vigorous exercise while yet a boy at college. He continued this daily, and after a time began to lift weights, then barrels of gravel to which he could add a little more from day to day. The use of the muscles of the body not only increased their strength, but they were disciplined so that he could use them in the desired direction, as referred to in speaking elsewhere of the blacksmith's boy. It should be stated also, that he practiced temperance in eating and drinking—eating but moderately of nourishing food so as not to overtax the stomach, and abstaining from liquors, tea, coffee, etc., which give a temporary stimulus, always followed by a corresponding depression. And just here let us say to our boys on the farm, there is nothing so good to give you vigorous health, strength, and "good feelings," as your daily toil—holding plow, carrying wood, picking up stones, and so on. Why, when sixteen years old we spent a winter at an Academy, where there were a lot of City boys, who were larger than we were, and delighted in making sport of the "green farmer boy.' We remember taking two of them by the collar one in each hand, and holding them so strongly that they could hardly move. This came from long practice at wrestling——with the plow-handles on stony ground, and among stumps and roots in new land. (That was a good while ago, but those strong muscles, and the vigor of constitution, are not lost.) Whatever a man is to do in after life, the very best *preparation* is thorough active labor on the farm, with the plain substantial food of the farmer's table. Nearly all of the really successful men in all kinds of business, and in every profession in this great city, and in other cities, are those who lived and *worked* on the farm until full-grown. And for the comfort of those who are so troubled at being poor, let us say, that nineteen out of twenty of the present successful farmers, as well as the successful men in other business and pursuits are the sons of *poor* parents. The fact that they were compelled to use their muscles, and brains, gave them the very strength and discipline essential to success. A boy or girl brought up without hard work, is like an arm carried in a sling; it is weak and puny. Remember, also, that just what strong exercise does for the body—mental exercise does for the mind. A person may inherit wealth, or may get it by good luck—but bodily strength, and strength of mind, can *only* be got by exercise.—Work away then my boys, and my girls too. Every day's work pays you something in increased vigor and health; every lesson learned, every hard problem worked out *without help*, adds to your strength and discipline of mind, and to your *real* worth.

About the Crown of England.

Few persons have any idea of the brilliancy and cost of the Imperial State Crown, or Cap, worn by Queen Victoria on certain State occasions. Here are a few interesting items: It was made in 1838, by Messrs. Rundell & Bridge of London. It weighs 3 pounds, 3¾ ounces, troy; or a little over two and four-fifths pounds avoirdupois. It contains **3,273** jewels, consisting of 2,783 diamonds, 277 pearls, 17 sapphires, 11 emeralds, and 5 rubies. They are catalogued thus: 1 large ruby irregularly polished, 1 large broad-spread sapphire, 16 sapphires, 11 emeralds, 4 rubies, 1,363 brilliant diamonds, 1,273 rose diamonds, 147 table diamonds, 4 drop-shaped pearls, 273 pearls. These are all placed upon a cap of crimson velvet, with a border of ermine, and lined with white silk. The jewels are arranged in the form of bands, festoons, arches composed of diamonds arranged like oak leaves and acorns, one large cross, four Maltese crosses, etc.....Several of the most precious jewels belonged to former crowns, and some of them have been in possession of the Royal family for 500 years or more. As men estimate, the value of the crown amounts to many millions of dollars. For real utility in itself, it is of infinitely less value than three pounds of iron. To a man cast away upon a desolate island, the jewelled crown would be of no account, while three pounds of iron, in the form of steel, fashioned into hatchet, knife, needles, etc., would add immensely to his comfort by enabling him to obtain food and shelter, and perhaps the means of escape.

PREMIUM LIST,

For 1862---Vol. XXI.

Or Pay to Voluntary Agents who will attend to collecting names of new and old subscribers to the Agriculturist, and forwarding them to the Office.

☞In selecting articles for premiums, we have aimed to get such as are *useful*, and as have been most frequently called for by our readers. ☞WE WISH IT DISTINCTLY UNDERSTOOD *that these premiums are offered in good faith—no cheap, trashy, imperfect, poorly made, or second-hand thing, will be sent out, but each article offered, is the best of its kind, and every one will be selected by the publisher from the very best manufactured. They will be the best sold in the market at the prices named.*

☞ Every person collecting names for premiums, should send two copies of each list of names—one of them marked "For Premiums," and also with the name of the sender.

☞ The premiums are offered for subscribers for Volume XXI (1862), *whenever received.* Canvassers will have time for completing their lists, but the premium will be paid as soon as any club is made up—if duplicate lists are sent. ☞ Clubs need not be all confined to one Post Office.

Table of Premiums for 1862.

Names of Premium Articles.	Price of Premiums.	Names at $1 each.	Names at 80 cts. each
2—Clothes Wringer, No. 2	$7 50	18	37
3—Clothes Wringer, No. 1	$10 00	23	48
4—Sewing Machine, (Wheeler & Wilson)	$45 00	90	130
5—Sewing Machine, (Wilcox & Gibbs)	$35 00	69	98
6—Aneroid Barometer	$7 50	19	44
7—Hydropult	$12 00	30	48
8—Five Octave Melodeon (best)*	$75 00	125	237
9—4½ Octave Melodeon (best)*	$60 00	104	182
10—Four Octave Melodeon (best)	$45 00	90	130
11—New Cyclopedia, 16 volumes	$48 00	96	140
12—Worcester's *Unabridged* Dictionary	$7 50	18	40
13—Five back Volumes Agriculturist, *p.p.*	$5 60	16	30
14—Four do do do do	$4 48	13	26
15—Three do do do do	$3 36	10	20
16—Two do do do do	$2 24	.	15
17—One do do do do	$1 12	..	10
18—Windsor & Newton's Paints	$2 50	..	20
19—Osborn & Hodgkinson's Paints	$1 50	..	15
20—Hand Corn Sheller (best)	$6 50	21	40
21—Straw and Hay Cutter (best)	$8 00	24	48
22—Best Subsoil Plow (2-horse)	$8 00	24	48
23—Various Books—*See terms below*			
25—Youth's Chest of Tools	$13 00	28	60
26—Gentleman's Chest of Tools	$20 00	43	80

* *See Advertisement, page* 94.

Premiums. 2, 3.—Wringing Machine.

We place this first, for it is nearly new, and one of the most useful articles for every family. The saving to garments would soon pay the cost of the implement, to say nothing of the saving of woman's labor. The machine is set upon the side of any tub; the garments drop out into a basket. A child can quickly wring out a tub full of clothes—No. 2, costing $7.50, is just the thing for common family use.

Premium No. 4—Sewing Machine.

90 Subscribers at $1 each, (or **130** at 80 cents each,) will entitle the person sending them to *Wheeler & Wilson's* best **$45 Sewing Machine,** (including **Hemmer**), new from the factory, and of the very best make. There is no better family machine than this made, as we have proved by nearly *four* years' use in our own family, in connection with other machines. We want no better.—Premiums 4 and 5 will be selected new at the manufactories, be well boxed, and forwarded without expense to the recipient, except for freight. Full instructions sent for setting up and using.

Premium No. 5—Sewing Machine.

69 Subscribers at $1 each, (or **98** at 80 cents each,) will entitle the person procuring them to *Willcox & Gibbs'* **$35 Sewing Machines,** including a set of **Hemmers.** This is the best machine of its kind, (sewing with one thread,) and has several points superior to other machines. It is neat, well made, simple in its operation; and having tested one in our own family for more than a year, we think highly of it, and can recommend it to those who can not afford to buy the higher priced double-thread machines.

Premium No. 23—Good Books.

Here is an opportunity to get a good library at little expense. Any person getting up a club of **16** or more names, may choose any desired Books from the list advertised on page 91, *to the amount of* 12½ *cents for each name sent at* 80 *cents*, (or 33⅛ cents for each name sent at $1); the books will be *delivered to the recipient free of all expense for postage.*

☞For descriptions of other premiums see Jan. No., page 28.

Market Review, Weather Notes, etc.

AMERICAN AGRICULTURIST OFFICE,
New-York, Wednesday Morning, Feb. 19, 1862.

*** The materials for this review are furnished specially for the *Agriculturist* by a reliable man of long experience, who, throughout the year, spends the whole of each business day in the markets, watching the transactions and collecting information, and we flatter ourselves that this report is one of the most correct anywhere published.

The Breadstuff Markets have been comparatively quiet for a month past. The condensed but comprehensive tables below show at a glance the transactions—including receipts, sales and exports. The table of Current prices indicate the change in selling values. Both Wheat and Flour are somewhat dearer. The recent Foreign advices have been encouraging to exporters, and they have also been favored by low rates for freights, and the greatly advanced value of foreign exchange. The bills drawn against shipments of Breadstuffs to England, which were hard to sell at 102@103 only a short time ago, have recently been in demand at 110 to 113@114. The receipts of Flour and Wheat from the interior have, taken together, been below those of the previous month, and decidedly less than for the corresponding period last year, as shown in tables 1 and 2, while the exports have been much larger this year, as seen in table 3. This has diminished the stock on hand, while the foreign demand is increasing. Holders of Breadstuffs are therefore firm, and with apparent good reason look for still better prices, especially as all our advices from abroad indicate the continuance of the heavy foreign demand which we have all along predicted, while no large addition to city supplies can be expected before the opening of the canals. Many foreign orders, recently received, have been limited to such rates that they could not be filled, with the views held by owners here, which has restricted the transactions....Corn has been quite freely offered, and prices have declined. The demand has not been very active, and at the close the market is quite heavy, though holders are very reluctant to make any concessions to buyers....Rye has been in lively request for export, and has advanced.... Barley also advanced materially early in the month, but has recently been less sought for, and is lower again ... There has been less doing in Oats, which are cheaper.... The success of the Union forces, on land and sea, have had a very significant influence on the market for Cotton, which has fallen off in value, on an average, about 7c. ℔ lb.—the market closing heavily, with a downward tendency....There has been a very large business transacted in Provisions, for both immediate and future delivery, at improved prices for Pork and Beef....Wool has been in limited demand lately, and low and medium grades have declined....The movements in other branches of trade have been moderate. The price table shows any changes in values.

N. Y. Live Stock Markets.—THE CATTLE MARKETS.—There have been five weekly market days since our last report, at which the offerings have averaged, 3,718 head: total 18,693. These have about equalled the demand. Snow and ice have prevented the prompt arrival of stock trains and confused the markets somewhat. At the market to-day (Feb. 20), with 3,894 receipts for the week, good nice killing steers have sold at 8½c.@9c. ℔ lb. estimated dressed weight; the next class 7¾c.@8¼c.; common animals, 7c.@7½c.; and poor thin steers, rough oxen and dry cows, 5½c.@6½c. Most of the sales were between 7½c.@8½c.; the average being 7¾c.@8c., or a slight advance from five weeks ago. Some extra cattle have been sold at 10c. during the month.

Veal Calves.—Receipts for the past 5 weeks number 1,563, or 312 per week. They have sold readily at ½c. advance or 5½c.@6c. ℔ lb. live weight, for the best calves, and 4c.@5c. for poor to fair veals.

Sheep and Lambs.—Receipts continue about as last month, or 8,020 per week. Market slow, just now at a decline of ½c. ℔ lb., from the figures of last month. Prime fat sheep are worth 4¾c. ℔ lb. live weight, extras 5c. Fair sheep 4½c. Some stock left over.

Live Hogs.—Receipts have fallen off materially since last month, the weekly arrivals being 23,969. Prices have advanced ½c. ℔ lb. Stock selling about as fast as received at 3¾c.@4c. for prime corn-fed hogs.

The Weather, during a month past has been mild for Winter, the mercury at no time falling below 10°. Snow storms have been frequent giving two to three weeks of good sleighing. The changes have been frequent and sudden, with many cloudy or stormy days and the barometer has vibrated much and suddenly, ranging through a full inch.——OUR DAILY NOTES, condensed, read, *January* 21, clear, 1 inch snow at night—22, clear, fine—23, 24, cloudy with 3 inches snow and hail on night of 24th—25, N. E. rain, barometer very low (29.20)—26, 27, clear fine—28, clear A. M., ½ inch snow P. M.—29, fog, light rain at night—30, rain—31, clear, fine——*February* 1, N. E. snow storm, 4 inches—2, clear, fine sleighing—3, cloudy A. M., and 2 inches more snow, P. M.—4, cloudy—5, clear—6, cloudy A. M., rain P. M.—7 to 10, clear, fine, mild—11, clear, ½ inch snow at night—12, fine, warm—13, cloudy—14, clear, fine—15, cloudy A. M., with 1 inch snow P. M.—16, clear A. M., cloudy P. M.—17, rainy P. M.—18, cloudy A. M., clear P. M.—19, snow P. M., thunder shower at night—20, clear, windy.

Rain Fall.—The rain and melted snow for a month ending Feb. 15th, amounted to 5.14 inches.

Thermometer at 6 A. M., New-York.

[Observations carefully made upon a standard Thermometer (Fahrenheit.)—*r* indicates rain—*s*, snow.]

No. 42 Park-row, New-York City.

ROE'S WESTERN RESERVE
PATENT
PREMIUM VAT

With Improved Heater and Valves.
This well-known CHEESE VAT was first introduced to the Dairymen more than seven years ago, *several thousand* have since been sold throughout the country—*more than one thousand* the past season; numerous and valuable improvements have been added from time to time, to embrace everything wanted in a CHEESE VAT; and we believe it now is the most *complete, simple, durable, and convenient* Cheese-making Apparatus in the world. Our long experience enables us to warrant our VAT to give entire satisfaction. By getting one of these VATS, a single Dairyman in any part of the country will have as complete an Apparatus, as is used in the largest Dairying localities. The Cut shows the back side of the VAT when opened, after using; the tube on the end of the heater is for the escape of steam; the knob at top operates the valve.
ROE'S PATENT ADJUSTABLE EXPANSION CHEESE HOOP, a very nice thing; one hoop makes three sizes, and expands to lift off the cheese.
SEND FOR CIRCULAR TO ROE & BLAIR,
Madison, Lake Co., O.

MARBLEHEAD CABBAGE

And Other Seeds by Mail, Post Paid.

STONE MASON CABBAGE, the standard Cabbage in Boston Market. It is the most reliable for selling, large, hard heads, and for sweetness and tenderness of all the drumhead varieties. It is also an excellent variety to plant in June. I am daily receiving letters from persons in all the Loyal States and the Canadas of successful all the excellent qualities I have claimed for it. Packages containing one ounce of seed of my own raising, with directions for cultivation, 25 cents; one pound $2.00. Early Marblehead Turnip-rooted (French seed) 25 cents per ounce, this is an excellent variety for light soils and general cultivation. Large Drumhead Savoy, seed of my own raising, 25 cts. per oz. Hubbard Squash, purest growth, 12 cts., extra per Mary, 12 cts. per packet, $1 per lb. Purely Parsis Cauliflower, best early variety, 25 cents; Early Frame Cucumber, (small fruited,) 25 cents; New White Spine, 10 cts.; Squash Pepper, warranted true and fresh, 10 cts.; Tom Thumb or Sweet Corn, very dwarf, but reaches high, and bears well, 12 cents; Darling's Early Sweet Corn, best of the early sweet varieties, 18 cents; Darling's Mammoth Sweet, best of all the large varieties, 10 cts; Stowell's Evergreen Corn, excels all in keeping long in green state, 10 cents; French bush Lettuce, early, 6 cts.; Imperial Cabbage, 6 cts.; Mountain Sweet Watermelon, very excellent, 10 cents; Christmas Muskmelon, early and superior, 8 cents; Coles' Crystal White Celery, 10 cts.; Danvers Yellow Onion, 10 cts.; Dandelion Seed, 10 cts.; Early Sweet Marjoram, 6 cts. All of the above will be sold by the ounce or pound. Catalogues of every variety of garden and Flower Seeds, Trees, Shrubs, Bulbs and grass. Part of my seed is of my own growing, the remainder from reliable sources. JAMES J. H. GREGORY,
Marblehead, Mass.

The following at 50 cts. per dozen, $2 per 100, $10 per 1,000.

Alpine Bush White, Alpine Bush Red, British Queen, Bicton Pine (best white), Downer's Prolific, Georgia Mammoth (very promising), Hoomes' de la Belgique, Triomphe de Gand (in all respects the very best and most profitable).

The following at $1 per dozen, $5 per 100, $35 per 1,000.

Kitley's Carolina Superba, Kitley's Goliah (enormous size and late), Nicholson's Superb, Princess Royal (very promising).

PLANTS BY MAIL.

We will send to any post office address in the country, post paid, and carefully put up so as to carry safely, one hundred good plants of any of the above varieties, at the prices annexed. For instance, 100 Wilson's Albany for $1; 100 Trollope's Victoria, $1.50; 100 Triomphe de Gand, $2, &c.

☞ Any orders filled for plants by mail for less than one dollar's worth, of any one kind, and when less than 100 are ordered, *it must be at the dozen price.*

SELECT LISTS OF STRAWBERRIES.

Five Varieties and Five Hundred Plants for Five Dollars.

For $5 we will furnish 100 plants each of the following kinds: Triomphe de Gand, Trollope's Victoria, Burr's New Pine, Jenny Lind and Wilson's Albany.

Ten Varieties and One Thousand Plants for Ten Dollars.

For $10 we will furnish 100 plants each, of the following choice kinds: Triomphe de Gand, Trollope's Victoria, Vicomtesse Hericart de Thury, Fillmore, Downer's Prolific, Burr's New Pine, Jenny Lind, Cutter's Seedling, M'Avoy's Superior and Wilson's Albany.

Seven Varieties and Twenty Thousand Plants for One Hundred Dollars.

For $100 we will furnish 10,000 Triomphe de Gand, 5,000 Wilson's Albany, 1,000 Trollope's Victoria, 1,000 Fillmore, 1,000 Jenny Lind, 1,000 Cutter's Seedling and 1,000 Downer's Prolific.

For the above list, five per cent will be added for boxes and packing.

TRIOMPHE DE GAND.

5,000 for $45, 10,000 for $75, 20,000 for $100. For the $100 lot five per cent will be charged for boxes and packing.

WILSON'S ALBANY.

3,000 for $10. Large quantities at same rate.

TRIOMPHE DE GAND AND WILSON'S ALBANY.

For $100 we will furnish 10,000 Triomphe de Gand and 10,000 Wilson's Albany. Five per cent will also be charged for this lot, for boxes and packing.

TRIOMPHE DE GAND.

For description of this superb and unrivalled Strawberry see our Circular. We will furnish this variety, and the Wilson's Albany—the two leading varieties, at the above rates:

RASPBERRIES.

Brinckle's Orange and **Franconia**, $1 per dozen, $5 per 100, $30 per 1,000.

Fastolff, River's Large Fruited Monthly, Knevitt's Giant, Hudson River Antwerp, Red Antwerp, Yellow Antwerp, Allen's Hardy, 75 cts. per dozen, $3 per 100, $25 per 1,000.

Improved American Black Cap, 50 cts. per dozen, $3 per 100, $25 per 1,000.

SELECT LISTS OF RASPBERRIES.

For $10 we will furnish 100 **Brinckle's Orange,** the finest flavored Raspberry, as well as one of the largest, most beautiful, and productive.

100 **Franconia,** a very large red berry, of good flavor, attractive and enormously productive.

100 **Improved American Black Cap,** much larger, more juicy, better flavored, with fewer seed, and every way superior to the common Black Cap. The plant is entirely hardy and very productive, and the fruit is much sought after in the market.

The above kinds include the three colors, orange, red and black, and furnish a pleasant variety in flavor. We regard them as the best for amateurs, and the most profitable for market culture.

For $100 we will furnish 1,000 **Brinckle's Orange,** 1,000 **Franconia,** and 1,000 each of any other three varieties in our general list, adding five per cent for boxes and packing.

On the same terms, we will furnish 5,000 **Brinckle's Orange** or 5,000 **Improved American Black Cap.**

BLACKBERRIES.

New-Rochelle, $1 per dozen, $5 per 100, $25 per 1,000, $100 per 5,000.

Dorchester, 75 cts. per dozen, $4 per 100, $25 per 1,000.

Newman's Thornless, 50 cts. per dozen, $3 per 100, $20 per 1,000.

We will send 100 each of the above three kinds for $10.

Each package of Strawberry and Blackberry plants will contain printed instructions for cultivation.

For prices of **Grapes, Currants, Gooseberries, Rhubarb, Asparagus, &c., &c.,** see our Circular, which will be sent to all applicants, enclosing stamp.

CHOICE FLOWER AND VEGETABLE SEEDS,

Mostly Imported the present Winter from the most celebrated French, German, and English Growers,

AND OFFERED FOR SALE BY

JAMES VICK, Rochester, N. Y.

I take pleasure in offering to the lovers of beautiful flowers and choice vegetables my New List of seeds for 1863, imported mainly from the best growers of France, Germany, and England, and which I believe to be unsurpassed by anything ever offered to the American public. My importations embrace all that is old and valuable, as well as everything new and rare, regardless of cost. These seeds are put up in neat packages, offered at a moderate price, and afford the amateurs and the florists of the country a rare opportunity to obtain the floral treasures of Europe as well as the choicest of its vegetable productions.

ILLUSTRATED CATALOGUES SENT FREE TO ALL WHO DESIRE.

Every Variety of Tomato.

Large Red, Large Yellow, Apple and Peach, Red Plum, Yellow Plum, Red Fig, (sometimes called Pear,) Yellow Fig Cherry, Lester's Perfected, New White French Tree Tomato, the new upright variety. Packages of seed of all the above choice varieties, will be forwarded, post-paid on receipt of one dollar. French Tree Tomato 30 cts. per package; New White, 15 cts.; Lester's Perfected 12 cts.; Large Red 25 cts. per ounce. *Every variety of Garden Seed for sale.* Catalogues gratis. Packages warranted to reach all who purchase. JAMES J. H. GREGORY, Marblehead, Mass.

OUR LATEST IMPROVEMENT:
PRINCE & CO.'S GRADUATED SWELL.
Patented September 17th, 1861.
This is an entire new idea, and its want has been noticed by all acquainted with Reed Instruments. The old Swell could never be made to operate gradually; the instant the pedal was touched for opening it, the change would be instantaneous and abrupt.
Our NEW SWELL is constructed on scientific principles, and we are satisfied, by our making study and experiments, that it is the only one by which the tone of Reed Instruments may be graduated from a mere whisper to the full power of the instrument, and vice versa. The volume of tone is also very much increased by this swell, and is now all that we could desire.
This, in connection with our DIVIDED SWELL, (which we patented in 1855,) will be added to all the Melodeons which we manufacture in the future, and without extra charge.
The other feature in our Melodeons is the IMPROVED VALVE OR PALLET, being a combination of cloth and leather, prepared expressly for the purpose. This valve we have used for the past three years, and we find it to be the very thing that has been so long needed as a substitute for the India Rubber Valve, which has been in use ever since Melodeons have been manufactured, and which has caused so much trouble by the ill-health and sticking of the India Rubber. All of our instruments are now finished with this improved valve, and we can recommend them with confidence.
Persons unacquainted with the Melodeon and its history, will bear in mind that we are the pioneers and largest manufacturers, not only in the United States, but in the world. We commenced the manufacture of Melodeons in the fall of the year 1847, and since that time have finished and sold

TWENTY-SEVEN THOUSAND!

These instruments are now in use mostly in the United States and Canada, but also in Europe, Asia, Africa, South America and the West Indies, and from all these quarters we have the most flattering testimonials of the high estimation in which they are held. At all Industrial Exhibitions they have invariably been

AWARDED THE HIGHEST PREMIUM!

wherever exhibited in competition with others. We shall take pleasure in forwarding by mail (on our own expense) to any address a Catalogue, in which every instrument we manufacture is fully described, and illustrated by elegant engravings.
☞ All Melodeons of our manufacture, either sold by us or dealers in any part of the United States or Canada, are warranted for perfect in every respect, and should any repairs be necessary before the expiration of five years from the date of sale, we hold ourselves ready and willing to make the same free of charge, provided the injury is not caused by accident or design.

HOW OUR MANUFACTORY IS CONDUCTED.
As we are the pioneers and leading manufacturers of Melodeons in the world, we have, of course, the advantage of securing the services of the best mechanics in the business, and very many of our workmen have been with us since we commenced the manufacture of Melodeons.
We employ none but the most thorough mechanics, and have never had an apprentice in the establishment.
Our work is divided into thirty-nine different branches; each workman has his own part to perform, and is never allowed to change from one branch to another.
The different parts are separately inspected, and passed from one to another to add to other parts, until the Melodeon is complete.
The delivering of materials and inspection of work is attended by, first, the general foreman; second, a foreman of machines; third, a foreman and inspector of tuning; fourth, a foreman in the varnishing department. This, a superintendent of the wood department.
The duties of the foreman are onerous, it being his duty to select and give out stock, to carefully watch the making of the different parts, keep the departments evenly balanced, and, in fact, to have an eye to every thing, and keep everything straight.
We have mentioned the duties to show that the utmost care is taken in every department.

OUR REED DEPARTMENT.—Much of the good quality of the Melodeon depends upon having perfect Reeds. It is necessary to have the most perfect machinery to cut, bare, stamp, plane, &c., &c., as well as to use the utmost care in selecting metals, and using proper proportions for the composition of reed metal.
The superintendent of this department has been with us since the commencement of this business, and, being a practical workman, has originated, improved and perfected all the machinery for making our reeds, and there are no duplicates in any other manufactory.
From the fact that our reeds are celebrated for their uniformity, evenness and sweetness of tone, we very often receive orders for them, or solicitations from manufacturers to supply them with what they require; but as we never sell any part of our instruments separate, we always decline to fill such orders.
In case the reeds of our Melodeon should at any time be so unfortunate as to break a reed, they can, by informing us which it is, receive by return mail a new one properly fitted and ready to put in, free of charge.

☞ Agents for the sale of our Melodeons can be found in all the principal towns of the United States and Canada.

EXCELSIOR

AND
ANTI-FRICTION
HORSE POWERS.
These Mills and Powers took TEN FIRST PREMIUMS at WESTERN STATE FAIRS last year, and are justly considered superior to all others.
These Mills can be run by any HORSE, WATER, OR STEAM POWER. For grinding all kinds of GRAIN, SPICES, COFFEE, PLASTER, BONES, SOAP STONE, &c., they have no equal.
Large Mills are made for milling purposes requiring but ONE HALF THE POWER to do the work of large flat stone mills
The HORSE POWERS have many advantages over those of other manufacture.
See *American Agriculturist* for 1861, pages 257 and 268, also page 31, in this volume.
Agents wanted in every county. Rights for sale.

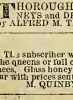
BEES.

TI subscriber will sell a large number of Italian Bees—the queens and colonies. Two hundred stocks of common bees. Glass honey boxes. Books on bee culture, &c. Circular with prices sent on application. Address

M. QUINBY, St. Johnsville, Montgomery Co., N. Y.



A Slight Cold, Cough, Hoarseness, or Sore Throat, which might be checked with a simple remedy, if neglected, often terminates seriously. Few are aware of the importance of stopping a Cough or Slight Cold in its first stage; that which in the beginning would yield to a mild remedy, if not attended to, soon attacks the lungs.

Brown's Bronchial Troches were first introduced eleven years ago. It has been proved that they are the best article before the public for Coughs, Colds, Bronchitis, Asthma, Catarrh, the Hacking Cough in Consumption, and numerous affections of the Throat, giving immediate relief.

Public Speakers and Singers,

will find them effectual for clearing and strengthening the voice.

Sold by all Druggists and Dealers in Medicine, at 25 cents per box.

Farmers and Gardeners, ATTENTION!

BRUCE'S CONCENTRATED MANURE.

OFFICE 25 PARK-ROW, NEW-YORK.

During the short time this manure has been before the Canadian public, the demand for it both in Canada and the States has so rapidly outran the supply, that the subscriber has been induced to establish a manufactory at *Cootake Point, N. J.*, where, with improved machinery and enlarged facilities, they will be enabled to meet promptly all demands; with their knowledge of the materials, and the satisfactory results produced, where ever used, they have to destitution in putting it before the public as one of the most valuable fertilizers in use. Its composition is such, that while it furnishes food to the growing plant, forces its growth to maturity, and puts it in the best condition for the reception of future crops, does not in any respect unlike guano, destroy other portable manures. *It is a soil improver as well as a plant improver.* It has been tried by various parties competent to form a judgment of its merits, and their testimony has been unfortunately in favor. We have several hundred certificates of Farmers, Gardeners, and Florists both in the U. S. and Canada. Below is one from Peter B. Mead, Esq., Editor of the Horticulturist:

NEW-YORK, Sept. 17th, 1861.

DUNCAN BRUCE, Esq., *Dear Sir*:

I have made trial of your Fertilizer during the past season, and the results warrant me in speaking of it in terms of commendation. I have tried nearly all the Fertilizers now in use, but none of them have given me as much satisfaction as your own. It produces a healthy and luxuriant growth, and is quite free from the disagreeable quality which renders the use of guano and some other fertilizers so dangerous, especially in a garden. I used your preparation freely over plots during the drouth of the past season with good effect. Guano applied in like manner almost invariably burns the plants up. I have never on the whole been partial to most of the artificial manures in the market, but my experience with yours, warrants me in saying that it possesses very high merit. It possible, you ought to establish a factory here as well as in Canada. Yours respectfully, PETER B. MEAD,
Editor of the Horticulturist, New-York.

LETTER FROM DOCTOR JUDD.

DUNCAN BRUCE, Esq., *Sir*:

I have used your fertilizer a fair trial, and find it an excellent material. It only requires to be once properly used, and then it will speak for itself. I have found it superior to any fertilizer I have heretofore used, and I have supplied pretty much all that have been presented.

RICHARD PENNELL, M. D.,
Member of New-York Horticulturist Society.

LETTER FROM PROF. C. THOMAS.

I have made repeated experiments, the past season, with Mr. Bruce's Concentrated Manure, and have found it recommend it as a most energetic fertilizer of both vegetable and flower plants. It was tried on various soils, dry and retentive, as well as a variety of vegetables, which quickly assumed a plethoric growth, and continued vigorous throughout the season, which has been unfavorable for fertilizers of organic plants. For Indian Corn, Tomatoes, Egg Plants and Early Potatoes it is capital.

Newark, New Jersey. C. THOMAS, M.D.

Send your orders direct to C. W. VAN DOREN, 25 Park Row, New-York. Factory Constable Point, N. J., opposite North-Amboy, Middlesex County. The Concentrated Manure is $40 per ton, put up in barrels of 200 lbs. each. We have also bags of 25 lbs. for those having Grape Vines and Flowers in a small way to attend to.

PROVIDENCE COMPANY'S CONCENTRATED BONE FERTILIZER.

This is the best Fertilizer, at the price, ever offered to the farmer.

It is composed of pure bone, ground fine, with other materials added to give it immediate effect.

It powerfully stimulates the plant from the moment the seed germinates until harvest.

It will not only fill the farmer's crib, but will enrich the soil. Try it.

It is packed in good flour barrels, and delivered to vessel or railroad, in New-York City, free of charge for cartage, at the following prices:

For one barrel, $2; two, $3 50; three, $5; four, $5 50; five, $8; six, $9 50; seven and over, $1 50 per barrel.

Two barrels will manure one acre of man in the hill.

Send your orders, inclosing the cash, by mail, to

GRIFFING, BROTHER & CO.,
No. 60 Courtlandt-st., New-York,
Who are Sole Agents for the United States.

GENUINE

SUPER-PHOSPHATE OF LIME,

Manufactured from **Raw Bones,** dissolved in *Sulphuric Acid,* with a few important additions, *at $45 per ton,* by

A. LISTER & BROTHER, Tarrytown, N. Y.

(For results of the present season see *American Agriculturist* for August, 1861, page 264.)

We guarantee every ton of our manufacture to be of uniform quality, and invite trials or chemical analysis.

We also manufacture Ground Bone, for sale by ourselves, BONE, the fine, medium, and coarse ground **Bone Manure,** for lasting and immediate effect upon the crops, and Bone Dust, for the coarse ground is particularly valuable for *Fruit Trees and Grape Vines,* which require a constant and lasting source of nourishment.

For sale in large and small quantities by

A. LISTER & BROTHER, Tarrytown, N.Y.
and their agent, F. LANGMAN, 159 Water-st., New-York.

ONE THOUSAND DOLLARS REWARD.

As Griffing Brothers & Co., were our Agents for two years, and are now advertising Poudrette with their brand, relying upon the reputation of the THE LODI MANUFACTURING CO., and the fact of having once been our Agents to assist them in the sale of theirs. And as it is different for people to discriminate always between the two.

I hereby offer a reward of One Thousand Dollars to any person, who can discover any other manufactory of real or pretended Poudrette, other than THE LODI CO.'s *the entire buildings of which will stand within the hoops any* that the LODI MANUFACTURING CO., put upon their barrels in the course of *one year*—said Factory to be within 100 miles of New-York City. JAMES R. DEY,
Prest. Lodi Manufacturing Co.

150,000 BARRELS POUDRETTE.

Send your orders early, and you will be sure to get them filled. Address GRIFFING, BROTHER & CO.,
Agricultural and Seed Warehouse,
No. 60 Courtlandt-st., New-York.

100,000 Barrels

OF THE

LODI MANUFACTURING COMPANY'S

POUDRETTE,

FOR SALE BY

JAMES T. FOSTER,

No. 66 Cortlandt-st., New-York.

The large facilities which they enjoy by exclusive contract for all the night soil of the City of New-York, and large capital invested in their extensive works, enable them to manufacture an article which is superior to any other fertilizer in market, taking *cost* and *yield* into consideration. It will be sold at the usual price of $1 50 per barrel for seven barrels or over, delivered free in New-York City.

Please take notice that the office and sale of this Company's Poudrette is changed from Messrs. Griffing, Brother & Co., No. 60 Cortlandt-st., to No. 66 CORTLANDT-ST.

Other brands of what purports to be Poudrette are in market, put up in barrels to resemble this. Beware of frauds—buy that only which has the brand of the Lodi Manufacturing Co. Any other article is comparatively worthless.

We call the attention to the following experiences of practical farmers, in different sections of the country:

NORTH PEMBROKE, Mass., Oct. 7, 1861.

James R. Dey, Esq., President of the Lodi Manufacturing Co.:

Dear Sir—The early autumnal frosts for several years past have seriously injured our corn crops, and rendered it necessary for farmers in this section to seek some fertilizer to give their crops an early start, in order to bring them to maturity in season to avoid that calamity. Having experimented with Guano, Superphosphate of Lime, etc., with indifferent success, in the Spring of 1861 I purchased four barrels of the Lodi Manufacturing Co.'s Poudrette, which I applied principally to my corn crop, with the most satisfactory results. This was the first Poudrette ever introduced into this vicinity. Last Spring I procured from your branch office in Boston about thirty barrels, for which I found a ready sale to my neighbors, who had witnessed the effect of my last year's trial, which, so far as has been tested thus, has given universal satisfaction. To farther test the efficacy of your Poudrette, this year I ploughed and hoed two acres of light, sandy soil, which had laid in grass about six years, (the last crop of which was very light.) This I planted with corn and potatoes, applying about four and a half barrels of Poudrette, and to other manures, always a handful of ashes to each hill at the first hoeing, and from present appearances we shall have a better crop than on a field of like soil where we applied twenty-five loads of manure to the acre. Its effects on garden vegetables are equally apparent. I am, very respectfully, yours,

HORACE COLLAMORE.

MERRILL, Me., Oct. 11, 1861.

Lodi Manufacturing Co.:

Sirs—I bought of your agents, Cross & Newell, two barrels of your Poudrette, and, in using the first, I got sick of it, and sold the other barrel. But the one that I used I tried the principal part on potatoes. I used about half a pint to the hill, and the yield was equal to those planted on manure at the rate of twenty loads to the acre. My neighbor, who bought the other barrel, says if he had bought five barrels more, he would have saved the price of twenty barrels.

Yours, &c., V. B. FALLS.

To the Lodi Manufacturing Co.: WALDO, Me., Oct. 12, 1861.

Gentlemen—Last Spring I bought of Cross and Newell one barrel of your Poudrette to experiment upon, but to my satisfaction in its utility. I put it on six rows of corn in different parts of the field, after hoeing; with barnyard manure, in the usual way—at the second time hoeing. Where I put the Poudrette the corn was twice as large as the rest of the field, and this now is one-third heavier, and has ripened about eight days earlier. I think it the very thing we want for raising corn in this country, and shall use it more extensively another year. WELLINGTON SHOREY.

SMYRNA, Del., Oct. 1, 1861.

Gentlemen—I had heard of the Poudrette manufactured by the Lodi Manufacturing Co., and thought I would try a small quantity on a lot of land intended for corn, and as I could not get it nearer than Philadelphia, I went and bought of the agent twenty barrels, and applied two barrels to the acre, dropping the corn and a handful of Poudrette in each hill. I left out a part of two rows, and put no Poudrette, to ascertain if there was any value in it, and noticed those two rows during the season, and where the Poudrette was used the corn was decidedly the best, and I have no hesitation in saying it is a good manure for corn. I am certain I made from one-third to one-half more by using it.

Yours, respectfully, JOHN G. BLACK.

CHESTER, Pa., Sept. 15, 1861.

To the Lodi Manufacturing Co.:

Gentlemen—I purchased this season of Messrs. Baker & Co., eleven barrels of Poudrette and one bag of Pruine, which I put on my corn. I marked the place where I put the Pruine, which, when the corn was ripe, was not now the corn where the Poudrette was as in much the best. Last year I used Allen & Needle's new Fertilizer, which did no good at all, as the corn done better without the manure. I think the Poudrette made by your Company the cheapest manure in use. Yours, &c.,

A. R. PERKINS.

The Company's pamphlet, containing directions for its use, with other valuable information and the experience of over one hundred farmers, will be sent free to any one applying for the same. Address,

JAMES T. FOSTER,

Premiums for Northern Grown Cotton.

One Hundred Dollars are offered for the best five specimens of cotton grown above latitudes 38° and 42°, this year. See particulars in February *Agriculturist*, page 64.

Subscriptions Still Date January 1st.

Unless otherwise specially ordered all new subscriptions received before June 20, will be entered from January 1st, and the back Numbers be forwarded.

Two Thousand for a Dollar! Twenty for a Penny!

Perhaps it may not be amiss to call the attention of those of our readers making up clubs, and of all those kind friends who are disposed to bring the *Agriculturist* to the notice of their neighbors, to a fact or two. Every number of the *Agriculturist* contains from **150** to **200** distinct articles and items, not reckoning the various suggestions in the Calendar of Operations. At the lowest calculation therefore, the current volume will alone contain over Two Thousand different articles, or suggestive items, the whole of which cost but a single dollar, or twenty for a penny. Now can any one fail to find among all these two thousand paragraphs, one or more hints that shall be worth more than a dollar—to say nothing of the amount of general information derived from reading the whole? To test this question, let any one who has read this or any other good journal for five years (or even one year) ask himself or herself, what would be my present information had I been without any of this reading. Our information is accumulating, and our modes of action are being daily changed, without our knowing how or why.

Those Good Premiums

Are still available to all. The descriptions (see page 90) are necessarily cut short in this paper. This month will afford a good opportunity to fill up incomplete premium lists, and to start new ones. The unusually large distribution of seeds will be our small incentive to new subscribers. We think this and the preceding two numbers are a sufficient guarantee that every subscriber will get his money's worth this year, to say nothing of the seeds "thrown in." ☞ Any person hereafter sending in new names not to go on any premium list, may, if desired, order an extra portion of seeds for himself.

A Good Lot of Advertisements.

The advertising pages are *well* filled, both in quantity and quality, and the reader will doubtless be well repaid for looking through the whole of them, to see *what* is offered, and *where*. (They are arranged in the pages somewhat in the convenience of the reader, and one page is likely to be as *new* and as good as any other.) No better or more select class of advertisements, as a whole, ever appeared in any paper. We could have readily filled the whole of this number, had we not shut out that large class who can afford to pay, and advertise most, because they give the least for the money. We scarcely found room for the good advertisements that were up to time—a strong indication of the revival of business hopes.

Note to Advertisers.—We want no advertisements but good ones—those from parties who will honestly do all they advertise to do. Distant parties, unknown to us personally, or by good repute, should send with their favors some indication of their good standing where they are known. In illustration, John Smith, of Western Minnesota, sends a glowing description of a new plant, which he offers at $1 each. We are afraid of him or his new plant, and how are we to know that it is not a catch-penny, or catch-dollar affair? We don't want to be accessory to any imposition upon our readers, and so must return the advertisement and money, though it may be all right. We mean to make our advertising pages as valuable for their selectness, as they are for the number of subscribers which they reach. On this latter point we are happy to say that the receipts of subscribers this year, so far, exceed those of any former year, and that the circulation of the *Agriculturist* is undoubtedly far ahead of that of any other similar journal in the world.

Mail-Lost Numbers Supplied.

It is hard for the Publisher to alone bear all the losses arising from the carelessness or over-sight of any of the 18,000 Postmasters and carriers who have the handling of the *Agriculturist* between the office and the subscribers. But since Uncle Samuel monopolizes the carrying business, and won't stand any losses, and we can't compel him to, we shall cheerfully send a second copy of any number when the first one mailed fails to reach its proper destination, after being notified of the fact. We suspect from the reports, that one of the packages sent to Providence, R. I., last month, has not got there yet. Let us know who are without that Number.

CLUBS

Can at any time be increased, by remitting for each addition, the price paid by the original members—provided the subscriptions all date back to the same starting point. The back numbers will of course be sent to added names.

Special to Postmasters—About Postage.

We have recently received four letters from four Postmasters. Two of these tell us very abruptly they "don't care anything for what editors say about postage;" they "get their instructions from Washington, and not from editors." *Query:* Do they ever learn *anything* from editors? Did they ever ask or receive any help from editors in getting their appointments? Well, as they have appealed to Washington, we have sent their letters there, and they will doubtless hear from them. The other two are polite letters, evidently written by men who are popular and obliging officers at home, though we have not the pleasure of their personal acquaintance. They say, "You are right in announcing that the postage on the *Agriculturist* is *six cents a year* when it weighs 3 ounces or less, but we weighed some numbers on very accurate balances, and when dry, and without wrapper, they still went *over* 3 ounces each. We therefore feel obliged to charge 12 cents a year, paid in advance." This is doubtless so, for after long searching, we have found a copy that weighs 3¼ ounces. It can only be accounted for in this wise, viz.: that at the paper mill, in starting on a new lot, a few sheets of uneven thickness run off before getting the pulp feeder exactly gauged, and whoever chances to weigh copies printed on these few sheets will find them over 3 ounces. We will now state that for years past we have only paid for 44 pounds per ream of 500 sheets (not 480,) which makes 88 pounds for every 500 copies of the paper, there being 2 sheets in each number. A little calculation will show that this is only 2 and 816-1000ths ounces to the copy, or allowing for weight of ink, the weight of each number is *less* than 2 and 9-10ths ounces. As our contract requires the paper to be made of uniform weight, and as the manufacturers would not be very likely to give us over 44 pounds to the ream when we never paid for more than 44 pounds, it is no longer that our numbers will overrun the three ounces, as a general rule. We respectfully ask our friends, the Postmasters, to look into the matter, and try the weight again, before charging beyond the one cent per copy, or *six cents a year*, if postage be paid quarterly or yearly in advance.

Bound Volumes—Binding—Covers.

We have complete sets of Vols. 16, 17, 18, 19, and 20, both unbound, and bound uniformly in neat covers with gilt lettered backs.

PRICES AT THE OFFICE.

Volumes 16, 17, 18, 19, and 20, *unbound*.....$1.00 each.
Volumes 16, 17, 18, 19, and 20, *bound*.....$1.50 each.

PRICES WHEN SENT POSTPAID BY MAIL.
(*They can not go unpaid.*)

Volumes 16, 17, 18, 19, or 20, *unbound*.....$1.12 each.
Volumes 16, 17, 18, 19, or 20, *bound*.....$2.00 each.

BINDING.—Sets of numbers brought to the office will be bound up neatly (in our regular style or binding the *Agriculturist for* 1862) at 50 cents each.

PREPARED COVERS.—Covers for binding, neatly made, with title, etc., gilt upon the back, for the binding of the 12 sheets by any bookbinder, can be furnished for Vols. 12, to 20 inclusive, at 25 cents per cover. *Covers can not go by mail.*

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, &c., &c., and to HOUSEHOLD LABORS. It has also an interesting and instructive department for CHILDREN and YOUTH.

A full CALENDAR OF OPERATIONS every month, THREE to FOUR HUNDRED, or more, illustrative ENGRAVINGS appear in each volume.

Over TWELVE HUNDRED PLAIN, PRACTICAL, instructive articles and useful items, are given every year.

The Editors and Contributors are all PRACTICAL WORKING MEN.

The teachings of the AGRICULTURIST *are confined to no State or Territory, but are adapted to the wants of all sections of the country—it is, as its name indicates, for the whole* AMERICAN CONTINENT.

A **German edition** is published, of the same size and price as the English, and containing all of its reading matter, and the numerous illustrative engravings.

TERMS INVARIABLY IN ADVANCE.

One copy, one year.....$1 00
Six copies, one year.....5 00
Ten or more copies one year....50 cents each.

☞ Add to the above rates: Postage to Canada 6 cents: to England and France, 24 cents; to Germany, 36 cents.

Postage anywhere in the United States and Territories must be paid by the subscriber, and is *only six cents a year*, if paid in advance at the office where received.

All business and other communications should be addressed to the Editor and Proprietor,

ORANGE JUDD, 41 Park-Row, New-York City

FROM THE STEAM PRESSES OF JOHN A. GRAY.

AMERICAN AGRICULTURIST,

FOR THE

Farm, Garden, and Household.

"AGRICULTURE IS THE MOST HEALTHFUL, MOST USEFUL, AND MOST NOBLE EMPLOYMENT OF MAN."—WASHINGTON.

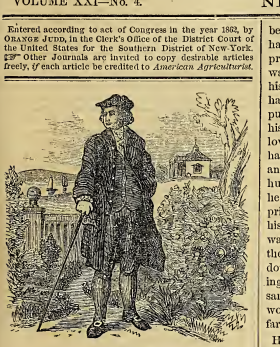
ORANGE JUDD, A.M., EDITOR AND PROPRIETOR. Office, 41 Park Row, "Times Buildings."

ESTABLISHED IN 1842. Published both in English and German.

$1.00 PER ANNUM, IN ADVANCE. SINGLE NUMBER, 10 CENTS. For Contents, Terms, etc., see page 128.

VOLUME XXI—No. 4. NEW-YORK, APRIL, 1863. NEW SERIES—No. 133.

Entered according to act of Congress in the year 1862, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York. [☞ Other Journals are invited to copy desirable articles freely, *if* each article be credited to *American Agriculturist.*]



April.

The last words of the Farewell Address of the Father of his country, read in every village and city in the loyal States on the late anniversary of his birth, are still lingering in our ears. "*Relying on its kindness in this as in other things, and actuated by that fervent love towards it, which is so natural to a man who views in it the native soil of himself and his progenitors for several generations, I anticipate with pleasing expectation that retreat in which I promise myself to realize, without alloy, the sweet enjoyment of partaking, in the midst of my fellow citizens, the benign influence of good laws under a free government.*" No wonder that he looked forward with such eager anticipation to his secure retreat upon the shores of the Potomac. Virginia had been the home of his fathers for four generations, and Mount Vernon had been the home of his affections, and the scene of his industries before he assumed the cares of State. Amid all his public cares at the head of the armies of his country during the war of independence, and at the head of the government after peace was declared, he never lost sight of his private affairs. There was a constant supervision not only of the general plan of farm operations at Mt. Vernon, but of all details, extending to the rotation of crops, the planting of particular fields, manuring, tillage and marketing.

Washington was kept so constantly in public life from middle age to his death, that it is very natural that we should know much more of him as a General and Statesman, than as a tiller of the soil. But we find among his papers and letters that he was quite as good at tilling the soil as at any of those tasks to which his country called him. He knew how to plan a campaign in the fields of husbandry quite as well as in the fields of war, and had he never been known as General and President, he would have stood in the front rank of the rural improvers and planters of his native State. It was by his thorough and systematic attention to his own private affairs, that he acquired those habits that made him so skillful a manager of public interests. He was known to the men of his time as the owner of one of the largest and loveliest estates in America, an estate that he had adorned and cultivated with his own hands, and made immensely productive by a system of husbandry of his own devising. It was because he had taken root in its soil, and grown to a princely stature, acquiring wealth and fame by his wise management at home, that he was wanted by the wise men of his time to manage their quarrel with the mother country. We have done well as citizens to recall his political teachings in the farewell address at the recent anniversary of his birth. There are some things noteworthy in his life at Mt. Vernon, to which we as farmers shall do well to give heed at all times.

He was an enthusiastic lover of rural life, regarding the noble art of "*agriculture as the most healthful, most useful, and most noble employment of man.*" It was always a sad day, whenever he turned away from the rich landscape beauty of the Potomac, from the beautiful lawns sloping down to the river, from the winding walks and shrubbery, from the fruit and flower garden planted by his own hands, and from the broad acres rendered productive by his skill, for the artificial life of the city, and the corrupt moral atmosphere of scheming politicians. No day was so joyful to him as that which welcomed him to his farm. Is there not a rebuke here for the multitudes who are turning their backs upon the old homestead, exchanging the plow for the yard stick, a certain and honorable means of subsistence for the golden visions of hazardous speculation? In *his* view, there was nothing like farm life. In *their* view, anything else is better than farm life.

He gave a minute personal attention to all the details of his farming operations, carrying out a well planned system. His Mt. Vernon estate consisted of about 8000 acres, of which over 2000 acres divided into five farms were under cultivation. He did not suppose that the farm would take care of itself, and support him without his planning and management. Sparks, in his biography, says of him, "With his chief manager at Mt. Vernon, he left full and minute directions in writing, and exacted from him, a weekly report, in which were registered the transactions of each day on all the farms, such as the number of laborers employed, their health or sickness, the kind and quantity of work executed, the progress of crops at the various stages of their growth, the effects of the weather on them, and the condition of the horses, cattle, and other live stock. By these details, he was made perfectly acquainted with all that was done, and could give his orders with almost as much precision as if he had been on the spot. Once a week, regularly, and sometimes twice, he wrote to the manager, remarking on his report of the preceding week and giving new directions. These letters frequently extended to two or three sheets, and were always written with his own hand. Such was his laborious exactness, that the letter sent away was usually transcribed, from a rough draft, and a press copy was taken of that transcript, which was carefully filed away with the manager's report, for his future inspection. In this habit he persevered with unabated diligence, through the whole eight years of his Presidency, except during the short visits he occasionally made to Mt. Vernon, at the close of the sessions of Congress. He moreover maintained a large correspondence on agriculture with gentlemen in Europe and America. His thoughts never seemed to flow more freely nor his pen move more easily than when he was writing on agriculture, extolling it as a most attractive pursuit, and describing the pleasure derived from it and its superior claims, not only on the practical economist, but on the Statesman and philanthropist."

Here was undoubtedly the secret of his success as a farmer. No business can be made to pay unless a man will give his close attention to it. If a man holds his lands as a speculation, and is always ready to sell out to the first man who offers him a handsome advance, he can not expect to make money by the culture of the soil.

He not only gave close attention to his business, but he managed his lands skillfully. He was a *progressive farmer*, making free use of books and correspondence, as well as his own experiments, to advance himself in his favorite art. He quickly observed that the system of culture prevalent among his neighbors, was fast exhausting their lands and making them of no value. At a time when they were thinking of abandoning their cultivated fields, he adopted a most excellent system of rotation of crops; and substituting grains, grass, and root crops for tobacco, he soon restored the soil to good condition, and found his income increasing, while his neighbors who pursued the old system grew poorer. Every field was mapped out, and the crops assigned to it, for several years in advance.

How completely this peaceful farm life filled the cup of his bliss, we see in his letter to Oliver Wolcott: "....To make and sell a little flour annually, to repair houses fast going to ruin, and to amuse myself in agricultural and rural pursuits, will constitute employment for the few years I have to remain on this terrestrial globe. If also I could meet now and then the friends I esteem, it would fill the measure and add zest to my enjoyments; but if ever this happens, it must be under my own vine and fig tree, as I do not think it probable that I shall again go beyond twenty miles from them."

Calendar of Operations for April, 1862.

[A glance over notes like the following will generally call to mind some piece of work that would otherwise be forgotten or neglected. The remarks are more especially adapted to places between 38° to 45°; but will be equally applicable further North and South, by allowing for latitude.]

Farm.

April with us is not the rainy month it is in England, where the proverb "April showers bring May flowers," originated, and like other proverbs has a foundation in truth. We frequently experience a period covering three to five weeks in March and April of comparative exemption from rain. Our roads become settled, the fields fit for the plow, the ground warm and ready for the seed—in short we have a *seed time*, when grass, grain, potatoes, and carrots, may be profitably put in, and much land prepared for crops. We counsel all farmers to bear this most important fact in mind, and to make good use of this period, which may be short. Remember, too, the cold rains which follow, and often last during the whole month of May, when plowing can not be done, when nearly all the seed rots in the ground, and farmers are busy replanting, or with their hands in their pockets, mourning over the yellow, spindling blades here and there in their corn fields. Some land is never fit for the plow before the first of June, or still later. It is probably too late to begin to do much at draining this Spring; the ground will be too full of water, and time too precious; but it is never too late to see the necessity, and plan for having the work well done.

Barley needs a fair quality of soil; avoid wetness and dryness; set it follow some hoed crop, or sow on sward turned over in the Autumn and manured. Sow when the ground is ready, warm and mellow.

Buildings—The first warm weather should not pass without a thorough cleaning out, and clearing up of the buildings of the farm. Now is the best time for painting and white washing buildings, fences, and the like, no dust is flying, driving storms are not expected, the weather is mild, and the paint hardens before blistering sums.

Calves—When milk is worth more than 2½ cents per quart it is cheaper to bring up calves upon gruel and skim milk than to let them suck the cow. Give, at 2 or 3 days old, new milk warm from the cow, then gradually add a portion of skim milk, and gruel of shorts, rye, oat or barley meal scalded and well soaked.

Carrots—Sow early in deep, warm, rich mellow ground, after some last year's crop calculated to kill the weeds. After rolling, sow in drills 8 and 20 or 24 inches apart, alternately, or 14 to 16 inches apart uniformly. The former method makes the use of certain tilling impiements more available. Use 2 pounds of clean last year's seed to the acre, tested beforehand, and thoroughly rubbed between the hands to prevent several seeds sticking together.

Cattle—It is important that cattle have some succulent food as warm weather approaches—rutabagas, mangels, sugar beets, carrots or cabbages—work cattle and cows both need it. A good currying or carding every day or two should not be neglected. Feed corn meal to both milch cows and oxen. This is the most profitable time of the year and they should lack nothing conducive to their health and comfort. Milk young cows *three* times a day; it increases the tendency to secrete milk and makes them better milkers in the end. Allowing any cow to go with a full dripping bag does not increase its capacity, but diminishes the quantity of milk secreted.

Clover may still be sown on Winter grain early in the month; and now is a very good time to sow it with grass seed where needed on permanent mowings or pastures.

Corn Ground—Prepare early if possible, turning under a good dressing of manure, but do not plant too early.

Cranberries—Prepare wet land for planting in May or June; deep upland soil, full of vegetable mold not subject to drouth, may be planted at this season, and the plants will get well established before dry weather.

Draining—If plans are not made and you are neither ready to break ground, nor yet well under way—walk about over your wet ground and do penance.

Flax—See article on page 107 of this number.

Grain Fields (Winter)—Roll with heavy roller, open dead furrows, and sow nitrate of soda, or guano and plaster, where the plants are puny or partly winter-killed. Go through and pull any docks or other coarse weeds which show themselves. On land very free from weeds, carrots may be drilled in, in rows 3 feet apart, and cultivated after the grain is cut; if the land is rich, a remunerative crop results—a good plan where grain is winter-killed.

Hired Men—Pay a man what he is worth, be generous and friendly in your treatment of him and you secure his love and make it for his interest to serve you honestly and well. Play the master to make him "know his place," and if he knows anything he will find another. A good man costs no more to board than a poor one, needs much less looking after, and is worth double.

Horses—Keep clean by the daily use of comb, card, brush and sponge. Wash their legs, feet and heads after hard labor, and rub them down with straw. It will surely pay. Feed generously; never over work them; be careful of straining them, and never abuse them. Keep mares near foaling in loose boxes, with plenty of bedding and give daily exercise, and some succulent food. Cut feed with meal upon it when horses are first put to hard work induces sweating and galling by the harness. It is better to feed oats at first.

Manure—The sooner it is under ground after removing from the barn-yard or cellar the better. It is much better to apply it very liberally than to till it *in*, than to scatter it over the whole farm. Use plaster, ashes, lime or perhaps guano, or superphosphate where the seed needs moderate encouragement, but do not waste stall manure in this way. Muck or sods and other partially, or easily decomposed vegetable matter, straw, bog hay, and the like, may be composted with one quarter stable manure or 2 cwt. castor pomace to the ton, and it will in 4 to 6 weeks, being twice or thrice worked over in the meantime, be ready for use, and an excellent manure. The addition of some leachings of the manure heaps, etc., will greatly improve it.

Mowings are greatly benefitted by rolling with a heavy roller; do it as soon as the water is off and they will bear the teams. Sow grass seed on thin places before rolling, and apply any top dressing afterwards. Clear of brush, stones, weeds, etc., while the ground is open.

Oats—Sow 2¾ to 3 bushels per acre when the ground is warm. See prize article in March *Agriculturist*.

Onions—Use American raised seed. Sow drills 12 to 14 inches apart in deep, rich, very mellow and warm soil. It is a good plan to sow onion and carrot seed together, and so when the onions are harvested the carrots will have the ground scarified by a harrow, and grass seed sowed with guano. Some such practice often pays well.

Plowing—Study and plan how to have the fewest dead furrows except on wet land, in which case make narrow lands. Back furrowing leaves fields which are tolerably regular, free from dead furrows altogether. It is done by striking a shallow furrow through the exact center of the field and plowing around it. It requires close calculation to avoid carrying the plow far across the ends. Lay out the field beforehand on paper and you will see.

Potatoes—The best success generally follows early planting, even for the main crop. There is a chance also of being able to sell new potatoes at a high price. Where rot is usual, use no fermenting manure, plant on an inverted sod with a little wood ashes in the hill, and plant an early maturing sort.

Poultry, provide boxes of ashes in which they may dust themselves, and if they are lousy add a small quantity of black sulphuret of mercury (black sulphur). Whitewash the hous and clear out the dung before it ferments. In tight houses this fermentation is often fatal to many fowls. Give them as much range as possible, but protect newly made garden beds from their scratching. Keep young broods dry and clean, and do not give a hen more chickens than she can cover while the weather is cool.

Roads and cart Paths—The repairing of these is about the first work that can be done, and nothing adds more to the comfort and good looks of a farm, than well kept roads to all parts of it.

Rye—The Spring variety is seldom sowed, except at the far North. It needs a little better quality of land and more seed than Winter rye.

Sheep—Breeding ewes must be kept separate from the rest of the flock; go through and "tag" the whole flock, removing all the filth adhering to the fleece; the wool saved will more than repay trouble. Provide shelter from rains.

Sorghum is now a standard crop at the West, and is likely to continue so. Prepare the land as for corn. See article in February *Agriculturist*.

Swine—Feed breeding sows succulent food, raw roots or cabbages in moderate quantities, and provide clean pens and abundant litter.

Tobacco—Sow as directed in last *Agriculturist*, a table spoonful of seed to the square rod, calculating a rod of seed bed to an acre of ground. It starts slowly. Prepare Tobacco land by plowing in a dressing of manure or rich compost,—reserving a good supply of the finest manure for a top dressing, that is to be harrowed in just before the plants are set out in June.

Tools—See Calendar in Feb. and March, p. 34 and 66.

Trees—Shade or fruit trees along the highways, and an abundance of fruit trees on the farm, show the good taste and good sense of the proprietor, who thus increases the value and comfort of his farm.

Water—A supply of running water is most valuable at the house, dairy, barn and stock yard. A pasture should have a constant supply. Springs, wells, rams, and windmills should be investigated, and some way provided for easily getting water at all times and almost every where.

Wheat—Plow for Spring wheat as early as the ground is dry enough, put the selected seed to pickle and soak some days before hand. Dry with slaked lime or plaster, and sow from the first to the middle of the month. See article in February *Agriculturist*.

Orchard and Nursery.

Tree buying and planting will be in order during this month. Early planting is desirable where it can be done. The roots suffer less if moved while still dormant. The ground settles about the roots, and the trees become established and commence growing before dry weather sets in. Look through the neglected or failing orchards, and see if there are enough recent plantings to make good the places of those trees which, after yielding well for half a century, are yielding to age. If not, by all means set out an assortment of apple, pear, cherry, and plum trees, before other Spring work presses. The prices of all kinds of orchard fruit have been sufficiently remunerative, during the past Fall and Winter, and for years past, to satisfy the most doubting that fruit growing pays well.

Give the old orchards a top-dressing of manure; a liberal dressing of slaked lime, or wood ashes, or both, spread about the roots will greatly promote vigor and fruitfulness. If pruning has been neglected, remove nothing in the apple orchard but dead branches and small sprouts at this season. Leave no brush heaps or loose stones scattered about. If the trees are generally failing it is better to begin a new orchard elsewhere rather than keep setting young trees in the places of old ones.

Drains in Orchards—Use rather large tiles, and lay them not less than 3 and if possible 4 feet deep. There is much less likelihood of roots stopping them up. Cover them with gravel or stones, to discourage the roots in their search after water or nourishment. Drains are of incalculable value on much land used for orchard purposes, particularly for peach and stone fruits.

Dwarf Pears—When well set and cultivated—are most desirable. They need as careful tillage as corn during the Summer, and must be sensibly pruned. Set out only those kinds which do well dwarfed, and which are known to succeed well in your vicinity, unless you choose to make experiments for the good of your neighbors. Select trees having one main stem, branching very low and of as conical a form as possible; some trees will not readily grow in the form of a cone, like the Winter Nelis, still the nearer they conform to it the better. The dwarf pear is an artificial thing, and must grow as we choose.

Grafting may properly be done early in the month. If the cions have not already been cut, secure them at once for it will be too late when the sap starts, unless they are selected with great care and inserted immediately. Cherries and other stone fruits if grafted at all must be at tended to very early in the month, and the cions removed from one tree and immediately inserted in the stock. Graft stocks in which buds failed or have been broken out.

Grapes—The vine so much neglected hitherto is now receiving the attention it merits, in almost all parts of our land. We have a few sorts which are adapted to culture every where, and the grape may be enjoyed by every one who owns or leases a square rod of land, from Maine to Texas. The soil should have been prepared last Autumn, decpened, enriched, and exposed to the frosts of Winter. If not done, dig large *holes*, or better, make a border 20 inches deep. Put the rich surface soil at the bottom, thoroughly mixed with any well rotted compost, and fill up with other surface soil from an old pasture or elsewhere. Above 41° of latitude select, Delaware, Hartford Prolific, Concord, and Diana—all good table grapes. Below this parallel of latitude the same thrive, and we may add, Isabella and Catawba. (See also article on page 116.) Clip off bruised or broken roots, and as a general thing, if the roots are abundant, reduce them to about a uniform length, so that they may be easily spread out in planting. Cut the tops back to two or three good strong eyes, plump and healthy. You will allow only the best one to grow. Put no manure in contact with the roots in planting, and set a good stake close by for protection now, and to tie the vine to when it grows. All the grapes named are hardy and gross feeders, except the Delaware, the best of all; this must not be set near any of the others or they will rob it of its food, and it will starve almost. It needs a rich soil, and the more it is pampered the better it rewards the husbandman.

inarching or grafting by approach may be performed so soon as the young wood begins to form, that is, when the leaves mature and perform their functions.

Insects—In going about among fruit trees, be constantly on the look-out for caterpillar eggs. They can readily be detected, gummed upon the twigs of the size of a quill and upwards. Pick them off and burn them. Remove any cocoons found in the branches, or under the rough bark; they are all nests of insect enemies.

Seeds of fruit and ornamental trees may be planted so goon as the ground can be worked, and is warm.

Nursery stocks budded last year, and not cut back, should now be headed down within two eyes of the bud. Plow out the rows as soon as the ground will admit, and remove the earth banked up against the trees last Fall. Begin early to transplant seedlings and stocks, and push the work vigorously as soon as the season fairly opens.

The nurseryman who has a stock of trees and plants ready for sale, should make arrangements to fill orders with all possible dispatch. Label carefully and truthfully.

Quince Stools, and those of ornamental shrubs used for propagating, may be dug about, manured, and the last season's growth layered as soon as the sap starts vigorously; it is best not to do it before. Such layering is now chiefly performed in August, when the wood is half ripe.

Stocks of all sorts for budding should be planted out early, to get a good growth for budding next Summer.

Trees most likely to thrive when removed are not those grown in deeply trenched and manured ground. Their roots are too long and wandering, unless they have been often shifted and root pruned. A moderately deep, hard soil, well manured and mellow on the surface, promotes the growth of a mass of small roots, which hold the earth, and such trees sustain moving much better than others.

Kitchen and Fruit Garden.

The most profitable labor expended on the farm is laid out here. But few farmers realize it. Their good wives know the value of the garden and its products, and we know this column will find among them careful readers. If you cultivate nothing else, have a good vegetable garden. Our language lacks an important thing in having no word for kitchen vegetables. So "truck" and "sauce" and "sass" are used, but without "authority." We are too much meat and meal eaters, and though we can hardly lay our lack of taste for vegetables, to our vocabulary, it is most important both in point of economy, health, and enjoyment of life, that we, farmers particularly, provide more and better fresh vegetables for our tables throughout the year.

The garden spot is better if underdrained thoroughly, the drains 3 to 4 feet deep and 2 rods apart; the soil deepened by trenching or deep plowing. For a large garden use the double Michigan swivel plow if you can. It leaves no dead furrows.

Artichokes—Remove suckers from old plants, strip off dead leaves, and plant in well dunged beds, 2 feet apart. Leave one, two, or three suckers on the old plant, according to the strength of the root and the soil. Seed may also be sowed at this season. (Do not confound with the "Jerusalem artichoke" which is a kind of sunflower.)

Asparagus—Fork in manure if not already done. Salt beds two years old. In cutting, use either an Asparagus knife which has a curve in the blade, and a long handle, or a long narrow bladed sharp knife, and cut 3 or 4 inches below surface, carefully not to hurt other sprouts, the growth of which is promoted by deep cutting.

Beans—Prepare poles. When new ones are procured it is advisable to soak at least the large ends, after sharpening and trimming, in a dilute solution of blue vitriol, several days or weeks even. They will last more than twice as long for it. Sow bush beans (early valentine or early six weeks) towards the last of the month.

Beets—Sow early in rows a foot apart; use plenty of seed and thin out for greens when the plants crowd. The early Bassano is the best sort for Summer use, and the Long blood for Winter.

Borecole, or Curly Kale—A plant of the cabbage kind used as winter greens. Sow and treat like cabbage. It bears the winter unprotected around New-York and much further north. Plant where it can be protected from game, which love its green leaves in Winter. See article on page 109.

Broccoli—Sow and treat like cabbage; there are early and late varieties. The flower, in a compact head, like cauliflower, is eaten.

Brussels Sprouts, or Rose Cabbage—It bears on a tall stalk multitudes of little cabbage heads like cabbage *roses*, very delicate. Sow early and transplant like other kinds of cabbage.

Borage—Sow for greens early, in dry soil, broadcast or in drills. To those who like this plant, it furnishes excellent summer greens. The flowers are showy.

Cabbage—Sow seed in open ground at any time, after the soil is warm. Transplant from hot-bed or cold frames for earliest crop; set 1½ to 2 feet apart. Early York is earliest. The Winningstadt far superior but a little later. Early green Savoy, a very desirable sort. Sow late varieties last of the month for late Summer and Autumn use; later sowing answers better for winter cabbages. Avoid the use of hog manure or any fermenting manure, or sowing where cabbages grew last year, if you would escape insects and club-foot.

Cauliflower—Treat like cabbages. There are early and late kinds. Early Paris and large late London are good sorts. They are the most delicious and delicate of all the cabbage family.

Carrots—Sow early in well prepared soil, in drills 1 foot apart. Mix the seed with double its bulk of fine dry soil or peat, to be able to sow it more evenly. For early use sow Early Horn, scattering the seed in a drill 2 inches broad. It is a very short and small variety, sweet and mild flavored, which bears crowding in the rows, thinning out as wanted for use during the summer, and is fit for the table as early as green peas come. This variety is equally good in winter, but the Long Orange is preferred because it yields better.

Celery—Prick out from the hot-bed to make stout plants for summer use. Sow seed in warm, very rich soil, in drills 6 inches apart for plants for main crop. The red varieties are most solid; the solid white more delicate; the Giant kinds are almost always hollow and pithy.

Celeriac—Sow as directed for celery, and if sown early, prick out in the same way.

Cardoons—Sow in warm mellow soil for transplanting into drills in June, where it can be bleached.

Chervil—Sow at intervals; it is used in soup.

Chives—Plant single bulbs 8 to 10 inches apart in borders.

Cold Frames, leave open except when very cold or rainy.

Cress (Garden cress, or Pepper grass)—Sow as early as possible, thickly in rows 6 inches apart. The early leaves are fit for a salad or relish in a very short time.

Cucumbers—See Calendar for March.

Egg Plants—Sow purple variety in hot-bed early, give considerable heat at first. The young plants are very sensitive. White egg-plants, are pretty but not worth cultivating except for ornament.

Garlic—Little used in American cooking, but desirable. The flavor is different from that of the onion. Sow seeds in rich mellow soil, or set out subdivisions of the bulbs, six inches apart.

Hops in the kitchen garden soon become a nuisance. Set a young vine, taken from the roots of a fertile plant, in some out-of-the-way corner in rich soil, and provide good tall poles, and a supply for the family will be had without further trouble.

Hot-Beds for farmer's use are quite as servicable made the first of this month as earlier. If the ground is dry, fill with the well turned and mixed horse manure—a pit 14 inches deep, and six inches all around larger than the frame. Make the frame of 1½ inch stuff—1 foot high on the front or south side, and the back high enough to allow the rain to run off freely from the sashes, which are usually 2½ to 3 feet wide and 5 or 6 feet long. Set the frame upon the manure, and spread evenly 4 inches of mellow soil. Put on the sashes and when a good heat is raised and the soil settled and leveled, it is ready for the seeds of early cabbage, cauliflower and the like, lettuce, tomatoes, peppers, egg-plant, radishes, etc.

Horse-radish—Dig for use, saving the long ends of roots and the branching crowns for re-setting; plant with a dibble in deep, rich, moist soil, 8 inches apart, in rows 14 inches apart. Almost any part of the root will grow.

Kohl Rabi—Sow in hot-bed early, or later in open ground, and treat every way like cabbage.

Leeks—Sow when the soil is warm; the seed may be mixed with onion seed, and the plants treated alike until the onions are pulled, when the leeks are left to grow.

Lettuce—Sow in hot-bed, and in the open ground, as early as possible—transplant to give room to head. In the former it will come forward and mature very rapidly. Stir the soil about the plants. Neapolitan cabbage, (Seed list 147) is a superior variety. Victoria cabbage, Mammoth India, and Curled Silesia, are all good.

Manure for the garden should be fine, well rotted, free from weed seed. If half muck, having lain in compost heaps all winter, so much the better. *Liquid manure*—Sink a barrel or half-hogshead tub in an out of the way but convenient place, to receive house slops and other liquid manure. Keep it well covered, and make frequent use of it to prevent putridity.

Mustard—Sow white variety in boxes (see page 101,) or in the open ground at any time for salad or for greens.

Mushrooms—Prepare manure for beds under cover, and procure spawn. It is commonly best to start mush room beds at this season.

Melons—Sow choice varieties of musk melons in hot-bed as directed for cucumbers. No. 76 of the Seed List is a good variety also Green citron, and almost any variety of Nutmeg melon.

Nasturtiums—Sow the yellow flowered, where the vines will have a fence or wall to ramble over and where the showy flowers may be seen, enrich well; sow last of April.

Okra—Sow after fear of frost, in drills 2 feet apart.

Onions—Sow white or yellow early in rich ground. See directions under Farm Calendar. *Potato onions*, best of all for the table, planting in mellow rich soil, one foot apart each way and keep the ground loose and clean. *Top onions* (rare-ripes) set 3 inches apart in rows 8 to 10 inches apart. The small bulbs raised from late sowed seed may be used in the same way.

Parsley—Cultivate the curled variety. Sow early in drills half an inch deep, on the border of vegetable beds, for which it makes a neat edging.

Parsnips—Sow in rows 14 inches apart, in very deeply worked and rich soil; the seed starts slowly.

Peas—Sow in succession, as soon as the last is well up. Let the Champion of England be your reliance. Dan. O'Rourke and Tom Thumb, (the latter dwarf,) and several others, ripen considerable earlier. Bush as soon as 3 inches high. See directions given last month.

Peppers—Sow in hot-bed or box, to transplant in May. There are many varieties used green for pickles, etc. The Large Bell for stuffing, Bullnose or Sweet Mountain for simple pickling, for which also the cherry is used; and the long varieties of all sizes used ripe for making Cayenne or red pepper and "pepper sauce."

Radishes—Sow in light sandy soil in a warm place, at intervals; water with liquid manure to force a rapid growth. The seed may be dropped in the ends of rows, or in any vacant spot, and a good return gained.

Rhubarb—Obtain tender thin skinned varieties for planting. Cover old crowns with a barrel with one head out, a tender blanched growth will result.

Salsafy (Oyster plant)—Sow early and cultivate like carrots. It needs deep tillage and rich soil, stands out over winter, and is excellent in spring.

Scorzonera (much cultivated in Germany, and called Schwarzwurzel,) is similar to salsafy; treat in a similar manner, but sow later.

Sea Kale—Sow seeds thinly, but in drills an inch deep, and a foot apart, to secure crowns for transplanting next Spring. Set roots two inches below the surface, two feet apart, in well manured sandy soil, worked eighteen inches deep, well dressed with salt.

Seeds—So far as possible test all before using, sowing them on wet cotton in a glass, or in moist soil kept warm. In sowing be careful to cover with fine soil and not lumps of earth. Burying seeds about an inch below the surface of the soil spread out between pieces of cloth, or put into cloth bags, is a very good way to sprout many kinds before sowing.

Small fruits that find a place in the kitchen garden such as currants, raspberries and gooseberries must be pruned and the soil, if to be not already done, and dug about and manured. Paving or spreading oyster or clam shells under gooseberries it is said prevents mildew.

Strawberries—The present is a good time to set out new beds, and to obtain new varieties, for propagation.

Spinach—Remove covering and use as wanted. Sow for successive crops in drills a foot apart.

Squashes—Plant summer squashes of dwarf sorts in hills 4 feet, the running sorts 6 feet apart. If the land is not quite rich put manure under the hills. Winter squashes need rich soil and room to spread; put the hills 6 feet apart, and manure in the hill. Hubbard and Boston Marrow and Crookneck are excellent standard varieties. No two varieties of cucurbitous plants should be raised near each other. The seed is not reliable if any two kinds are raised on the same half acre.

Tomatoes—Sow in hot-bed to transplant in May. When protection can be given, early plants may be transplanted in this month. Lester's Perfected and the Fejee, are both good varieties.

Sweet Herbs—Divide the roots of Sage, Lavender, Thyme and Rue. The mints of all kinds of Balm, etc., may be propagated by dividing or from the ground shoots which have rooted. Sow seed of Basil, Summer Savory, Clary, Sweet Marjoram, etc., where the ground is warm, in drills, near or further apart according to the plant.

Sweet Potatoes—See article on page 108.

Tools—It is important to clean garden tools as often as used, and as soon as they are laid out of the hands. See article on garden tools, page 116, and secure good ones.

Turnips—Sow early Flat for Summer use in light soil.

Winter Cherry—Sow in hot-beds or open ground and treat like tomatoes; they require scarcely less space.

Flower Garden and Lawn.

The love of flowers is as natural to a man as is his breath—but alas! the love of profit that may be counted in dollars and cents, leads too many to overlook the enjoyment which springs from so much purer and higher a source. A little taste and care, with a very little expense of time or money, will make the surroundings of the humblest cottage most attractive and beautiful; and the wealth of the Indies may be lavished for years upon glass houses and gardens, and still we shall have but just begun to see with what varied, delicate and gorgeous beauty of the floral world, nature will reward our care. Every one may have flowers.

Before laying out a new place, provide for a liberal garden spot, give it a warm sunny aspect, some shaded nooks, a good, well drained soil, and allow it a good share of manure. The soil must be well worked, mellow and free from weeds—But some nice flowers grow anywhere.

Annuals—Sow hardy sorts such as mignonette, portulacca, candytuft, phlox, coreopsis, daisy, clarkia, and larkspur of our seed list; also scabious, nemophila, eschscholtzia, hibiscus, etc. They require less covering when sown early in the season, and are often put too low in the soil. The more delicate the seeds, the finer should be the earth with which they are covered. Asters, petunias, balsams, gillyflowers, etc., may be sown in hot-beds, to be transplanted next month.

Borders are the first portions of the garden to be dressed, manured and put in order for the season.

Box Edgings—See directions given last month.

Bedding Plants—Harden them by free circulation of air in the houses or frames during this month.

Bulbs—Plant out those which have bloomed in glasses. Remove any covering or mulch allowed to remain until now. Hyacinths, tulips, and other imperials, as they come in flower, should be neatly staked up.

Carnations and Picotees—Harden those in pits by exposure, and plant out when the weather is settled.

Climbers—Prune and train Honeysuckles, Woodbines, Wistarias, and other woody climbers, and plant others.

Dahlias yield the finest bloom in the cool weather of Autumn. Hence it is not desirable to plant many before May. A few may be put in to secure sprouts.

Dicentra (Dielytra), a most beautiful flower in the border. Plant out and divide roots.

Draining—This is the best time to drain many gardens. Lay them under walks where the ground is at all wet.

Evergreens—Arbor Vitæ and Norway Spruce may be transplanted freely at this season; others in May or June.

Frames and Pits—Ventilate freely to harden off the plants and prepare them for setting out. Transplant from them in warm localities, when the weather has become mild and settled. If not too crowded, they will flourish best in boxes, until the open soil is dry and warm.

Flowering Shrubs—Plant the althea, flowering almond, azalea, chionanthus, flowering currant, deutzia, euonymus, holly, Japan quince, laburnum, lilac, pinkbells, phlox, rose acacias, snowberry, snowdrop, spiræa, tree peony, weigelia, etc. Early flowering shrubs give a finer bloom if transplanted as soon as ground is in working order.

Gravel Walks—Add gravel to old and new walks as needed. Clean out any weeds or grass, cover with gravel, rake smoothly, and press down with heavy roller.

Hedges—Set out privet, althea, hawthorn, Arbor Vitæ, etc., for hedges. Osage Orange and honey locust are of too rampant and coarse a growth for handsome screens or protection around dwellings and pleasure grounds.

Labels and Stakes—Provide an ample supply.

Lawns—Sow grass seed on thin spots, scarifying with a sharp rake, and roll. Top dress with guano water, or ammoniacal water from gas works, or with Chili saltpetre, ashes, plaster or superphosphate. Instead of a mixture of seed as formerly preferred, a single sort is now recommended, so that the lawn may present a uniform hue.

Manure heavily all the borders and flowers plots.

Perennials and Biennials—Plant seeds of Canterbury bells, forget-me-not, standing cypress, dwarf blue larkspur, and foxglove, of our seed list, and other hardy biennials and perennials, when we have settled weather and a warm soil. Some of these, like pansies and forget-me-nots, bloom the first season. Also divide and re-set, or plant out pinks, sweet williams, pœonies, lilies, phlox, etc.

Petunias and Verbenas—Procure rooted plants from florists and set in masses. Sow seed in the hot-bed.

Roses—The almost endless variety of monthly, remontant, and common sorts, enables the cultivator to secure a rich profusion and constant succession of bloom. Purchase and set out blooming plants, and such only as have a good reputation for hardiness and free blooming. The Remontant, sometimes called Hybrid Perpetual, will give good satisfaction. Plant out, prune and tie those trained to trellises or pillars. Uncover tender varieties buried or tied up last Fall when danger of frost is over.

Shade Trees—Plant deciduous sorts early. Many of our choicest fruit trees are beautiful as shade trees, for instance, the bigarreau cherries, the crab apple, and pears growing in uniform pyramids like the Buffum.

Tender shrubs and vines which were strawed up, or otherwise protected last Fall, may be uncovered. It is best to loosen the straw before removing it altogether.

Vines and Climbers—Plant bignonia, clematis, honeysuckles, ivy, trumpet flower, Virginia creeper, wistaria, moneywort, etc., and arrange on permanent supports.

Green and Hot-Houses.

As most of the plants will be removed to the open grounds next month, care should be used to harden them off in April. Dispense with fire in the Green-House when possible, and keep ventilators and doors much open. Forcing houses also require much less heat, and more air.

Bedding Plants—Propagate (by cuttings, and dividing roots,) an ample stock of verbenas, petunias, geraniums, daisies, pansies, salvias, heliotrope, fuchsia, heliotropes, etc. Expose by degrees to gradually harden them.

Camellias past blooming, should be pruned and washed.

Cuttings—Increase stock by cuttings. In the commercial house it is especially needful. Fuchsias, geraniums, myrtles, hydrangeas, camellias, jasmines, salvias, and most other plants will strike freely under glasses, with a sandy bottom heat.

Fuchsias—Increase the stock of this elegant flower by inserting a large number of cuttings.

Prune and head back all feeble stunted plants, or those of straggling or undesirable growth.

Insects increase rapidly, if not early checked. Hand pick, fumigate with tobacco, syringe with oil-soap water.

Seeds of desirable green and hot-house plants, such as geraniums, aloe, cactuses, ice-plants, euphorbias, cineraria, etc., etc., may be sown now in pots, plunged in the bark-bed, and covered with bell glasses, or in their absence with a pane of glass laid over each pot.

Shifting—Repot plants needing more room, cutting away diseased roots. See illustrated article, page 117. Give fresh earth to plants that do not require repotting.

Water freely, rapid growing and succulent plants; they require more than woody sorts. Add a very little guano or carbonate of ammonia to water for lagging plants.

Grapery and Orchard-House.

Grapes ought to be growing finely now; new shoots should be tied up as they extend. Those in earlier houses have already set their fruit, and the berries are of sufficient size to require thinning. Cut back the laterals above the bunches to three leaves, and remove shoots between the bunches and the main cane. As the berries swell, support the shoulders of the bunches by tying to the canes above. Syringe freely, adding sulphur to the water to prevent mildew. Vines which have only burst their buds, need to be kept horizontal to start evenly.

Mildew can be prevented by the free use of sulphur.

Peaches, Apricots and Nectarines—Remove superfluous shoots, and pinch in to prevent rampant watery growth. Thin out the fruit where it needs it.

The orchard house or grapery is often an excellent place to bring forward strawberries, string beans, etc.

Apiary in April.

Prepared by M. Quinby—by request.

Bees will now begin to bring in pollen; but a steady supply is not certain. On cloudy or chilly days the bees will not venture out; and a severe frost may destroy all the flowers for a time. The morals of our little favorites in such times are apt to suffer. Idleness with bees begets mischief, war and pillage. The "flour feed" may advantageously be given to keep them employed. But they will refuse to take it altogether very soon. Scrape the filth from the floor of the hive. See if there are clusters of dead bees among the combs; such should be removed. If they have remained long enough to mold, take out the comb, as far as it extends as well as the bees, quieting the bees with a puff of smoke occasionally. Colonies that are out of honey, can not be expected to obtain supplies from the flowers yet, for they get little else than pollen, and this will not sustain the old bees; they should be fed as required with honey or sugar syrup. Feed often, in small quantities, two or three times a week. Put it on the top of the hive or breeding box, open the holes and cover it close with a box, to prevent robbers having access. Do not feed promiscuously by setting honey where all can take it. It induces contention among the bees at home, and entires those of neighboring proprietors. Robbing may occur any warm day; on warm evenings they continue operations until dark, when it can be readily detected. You can also see where the honey is taken—most likely into the strongest colony in the yard —but one is stealing change the stands, setting each hive where the other stood. As it will be impossible to do this when several are engaged, it will be necessary to carry the one being robbed to some dark room, until several warm days have passed, when it may be returned, or take it away a mile or two, until all danger from further attacks are over. Keep the entrance to all weak hives properly contracted during this month. The moth worm may be found on the floor of the hive in considerable numbers; sweep out and destroy them all. Put up a wren box near the apiary, for such birds will pick up a great many of the worms, and will be on the look-out for them when you are away.

Many who have not the movable comb hive will want to procure Italian bees this season, and to know how to transfer from the old box to the movable comb hive at once, and not wait for new swarms with which to do it. Complete success with Italians can hardly be expected without some of these hives. The present season is perhaps as good a time as any to make the transfer, for there are fewer bees than at any other, and not much brood in the way. The directions given last year are about here. Select if possible a hive with straight combs; blow up into it a few puffs of smoke to keep the bees quiet, and carry it to the apiary. Invert the old box, and place all the bees that will go readily into an empty hive—one of the same size if possible, or made comfortably warm. Now pry off the side of the hive, and cut out the first comb, and lay it carefully, without bruising, on a few thicknesses of folded cloth. Lay over it the frame into which it is to be fitted, and marking the exact size, cut and trim the comb to fit into the frame; put it in and keep it there by winding twine around the whole. Straight combs are readily held in this way, but crooked ones will need narrow splints or sticks to hold the ends where they project. Keep the filled frames upright. All the combs as they are fitted and put in the new hive, should be in the same relative position as before, if possible, that the brood may be together and be protected by the bees. When all is arranged, the hive which have been shut up may be shaken out upon the top of the frames, and covered with a close box to keep them from flying, until they find the combs. Set it on the old stand, and the bees as they may be returned to the stand. Such bees as are on the windows, may be brushed into a box and shaken on the frames after the rest are put in place. If the day is pleasant, the window may be raised and the bees swept out, and they will return to the stand without trouble. Avoid opening the movable comb hives on cold mornings, or in chilly weather, lest the brood be injured. It is not safe either to open them in the middle of the day, as large apiaries when the bees are flying, as it might induce robbing any time before the flowers yield a full supply of honey. The best time appears to be just before they begin work in the morning.

Agriculturist Exhibition Tables.

GRAIN AND SEEDS.—Collection of Corn, W. S. Carpenter, Rye, N. Y.....California White Wheat, Mr. W. H. Ranlett, N. Y.... Rice Corn, Hiram W. Sutphen, Prospect, N. Y.....Sweet Corn (Seneca) yellow and white ears, and white Corn (Seneca) yellow Corn on grass land, with little manure, 150 bushels ears per acre, C. L. Bassett, Derby, Ct.. White Flint Corn; ears 14 inches long, 40 rows, and ears 11 inches long, 14 rows, A. P. Fonda, Paterson, N. J.... Guinea Corn and Red Onions, Willis J. Young, Oyster Bay, L. I.... Virginia Coffee or "Chick Pea" (*Cicer Arietinum*), O. Judd, Flushing, L. I. ....Large Pop Corn. Mr. Chase, Lockport, N. Y.....12 14 and 16 rowed Corn, Geo. Jas. P. Flint, Bloomfield, Conn.....18 rowed Red Corn, M. Pryer, Bowery Bay, L. I.....Scioto Corn, R. B. Sutton, Guilford, Conn.

FRUITS.—Winter Cherries (*Physalis Viscosa*) and Iron Apples, G. B. Hummelbaugh, S. L. Allen, Northern Spy Apples, and several seedling varieties, W. S. Carpenter, Rye, N. Y.....Rocky Mountain Currants (Varieties,) and Rocky Mountain Raspberries preserved in cans and bottles, J. B. Wolf, Denver City, Col. Ter.....Admonished Pears, Mr. Cornell, Flushing, L. I.....Apples—American Russet, Meadow Sweet, G. H. Banta, Tappantown, N. Y.....Iron Apples, G. Usher, Port Richmond, S. I.....Preserved Black Currants, Ebenezer C. Wheeler, Fairmount, N. J.....Pods of the Tamarind, by a Volunteer, Key West, Fla.....Chestnuts and Hickory Nuts, very fine, Geo. Smith, Walnut Creek, Ohio.

FLOWERS, ETC.—Beautiful bouquet of Skeletonized Leaves, Flowers and Seed Capsules, W. P. Heins, Woodstock, N. Y.....Beautiful bouquet of Dried Flowers, Everlasting Flowers, Grains, etc., from the same exhibitor....Everlasting Flowers, Mrs. Bushing, L. I.... Cut Flowers, Pansies, Violets, etc., fine, Mr. Cummings, N. Y.....Parlor Green-Houses, containing Ferns, Mosses, Lycopodiums, &c., Publishing, L. I.....Mrs. Cone.

IMPLEMENTS, ETC.—Mole Trap (the best we have seen, W. Norton, Heightstown, N. J.....New Flour Sifter, John VanGenthi, N. Y.....Model of Rotary Digger, J. S. Stevens, Coe's Corner, N. H.....Model of Reel, Halsted, Bye, N. Y. Fruit Baskets. J. R. Parks, Marlboro, Ulster Co., N. Y.....Model of Step-ladder, E. J. Swords Jr., Portchester, N. Y.

MISCELLANEOUS ARTICLES.—Oysters growing upon and showing strong attachment to a champagne bottle found in the sand, Mr. Feltheus, Bay Ridge, L. I.....Sorghum Molasses, John Manwearing, Mendota, Ill.....Bust of Washington, Thos. Keating, N. Y.....Chinese Opium Pipe, C. Hafra, N. Y.....Live Hen Hawk, M. Fleshham, Bay Ridge, L. I.....Corn Bread and Johnny Cake, Mrs. Haring, Monroe, Co., N. Y.....Cotton Bolls from Port Royal, S. C.....Cotton grown by Martha Yakey, Oakfield, Perry Co., Ohio.....Green Curled Kale, O. Judd, Flushing, L. I.....Dyfeman Potatoes, fine, S. B. Conover, West Washington Market, N. Y.... Vegetable Ivory Nuts. Mr. Chase, New-York.

Containing a great variety of Items, including many good Hints and Suggestions which we give in small type and condensed form for want of space elsewhere.

The Seed Distribution Soon to Close.—Owing to the cheaper postage, we provided nearly double the usual quantity of seeds, yet so great has been the call for them that the applications already in will nearly or quite exhaust many varieties, which can not be replaced this year. Any future applications should give a dozen or more numbers and we will send four or five parcels of such as we have left, beginning at the top of the list of numbers received. So far we have had our assortment full, except No. 215, of which we only received a very small part of our order, owing to its scarcity in Europe, and none can be obtained in this country, except in small retail parcels. All applications for seed to this date (March 20) will be sent off before March 31, and those previously applied for together with the express parcels, will go the first week in April. A few errors may occur in sending off half a million parcels to so many different persons, but our system is so perfect that very few mistakes can occur on our part.—We are sorry to report, however, that about 50 envelopes are defective in the address (name, or P. O., or State,) or in list of numbers. We must of course suffer for a supposed lack of good faith, for we can not even write to explain, as there is no means of telling where to direct a letter. The name is sometimes given with nothing more, but except in chance cases, we can not remember to which of the 17,000 post-offices in our books we must look for the name.—New subscribers hereafter coming in will be presented with the usual four or five parcels if a list of 13 or 15 numbers be sent to us to select from.

The "War Maps,"—We presume no excuse is needed for occupying so much space with Maps of the sections of our country occupied by the contending armies; the very great number of references to those already given, and the calls for more, indicate that they are just what is most acceptable to nearly all of our readers now. The map on page 121 gives a general and connected view of the Eastern section of the country, (see note in corner of map;) while the two maps on pages 124 and 125 give, on a large scale, two localities which are of present interest, *McClellan's* Division between *Washington* and *Richmond*, and *Burnside's* Division in *North Carolina*. The map in the *November Agriculturist* showed *Fortress Monroe*, and *Norfolk* and the vicinity; and the map in *February*, an enlarged section of the Coast and Bays of North Carolina. The map last month (*March*) showed the whole country between the Ohio River and the Gulf of Mexico, including the *Mississippi River* and *Valley*, *Nashville*, *Pensacola*, etc. The *November* number shows very fully the *States of Missouri*, *Kentucky* and *Tennessee*. The *December* number shows *Port Royal*, and *Beaufort, S. C.* In the *January* number are given enlarged maps of *Savannah*, *Fernandina*, *New-Orleans*, and a beautiful section map of the *Mississippi River from Cairo to Memphis*, including *Columbus*, *New-Madrid*, *Island No. 10*, *Randolph*, etc. Those who have preserved their copies can readily refer to nearly all points of interest. Any one of the above numbers missing can be supplied at the usual rate (10 cents).

The Crop-Report Statistics, proposed last month, page 73, promise to be very valuable. Farmers' Clubs, and many public-spirited persons, are taking hold of the matter. It is a project in which the whole country is deeply interested. Let us have names from every locality not yet reported. The blank tables will be distributed about the middle of April.

The Premiums,—The General Premiums on page 122 are all continued. We hope our readers will find many who will yet feel the need of the *Agriculturist* as the Spring work opens, and will feel able to take it, now that the prospects of the country are appearing so much brighter. Premium clubs may yet be filled up and new ones still be started for the present year

Who and Where ?—As a sample of others, here is a letter which speaks of 10 cents for a "Sept. No. 1858," etc. *But there is no name, or date, or legible post mark, any where on or in the letter, or in it,* to give the slightest indication *where* it came from, or *who* sent it. We are of course meekly waiting for the expected scolding.

The Advertisements Worth Reading.—Another large list of good advertisements will be found in this paper—almost all of them new ones. The necessity of printing the maps on one side of the sheet, has divided up the advertisements somewhat, upon five or six pages (123-4-5-6-7). Answers to many questions addressed to the Editors can be found in the advertising pages themselves. We take the more pleasure in thus referring to these business pages, because they are pretty thoroughly sifted. It sometimes "goes agin' the flesh," though good for the spirit, to refuse ten, twenty, fifty and even hundreds of dollars, for an advertisement that shows well on its face, but may *possibly* cover knavery.

Book Questions.—On our table are at least a hundred queries about books on agriculture, animals, fruits, flowers, and other topics, their cost, etc., answers to most of which can be found by referring to the starred list (*) on page 125.

Cotton Seed.—To numerous inquirers: We do not know of any large supply of the Upland seed in this vicinity. The seed stores sell it out by the pound, at about 25 cents per pound, to which 17 cents must be added if to be sent by mail. We laid in only enough for our seed distribution, last season. The Sea Island (smooth) seed is plenty, but not wanted for practical cultivation in the North. We put a little in our seed parcels, to be grown as an ornamental flower.

Pure Sugar Cane Seed Not Obtainable.—Answer to many inquirers: We are sorry to report that we can get no good seed, *known to be pure*. We ordered **2,000** pounds from France, if positively *pure* seed could be obtained; but our correspondents answer that, after diligent search, both in France and Algiers, they cannot secure any *known* to be unhybridized. Large quantities, supposed to be good, have been sent over here to different parties, but none of it could be warranted so. The same carelessness has prevailed in France and Algiers, as here. New importations will be made direct from China against another season. Our readers will be obliged to use the best seed they can obtain, and then trust partly to chance for its good quality.

Appleton's Cyclopædia.—Another volume of this noble American work is now upon our table, fresh from the press—(American Cyclopædia, vol. XIV., from REED to SPIRE; 858 pages.) This volume seems to be prepared in the same thorough manner as the previous ones. A few of the topics, noted at random in running over the pages are: Reformation, Reformed Dutch Church, Religious Orders, Reptiles, Resins, Respiration, Rhododendron, Rhubarb, Rice, Richelieu, Rickets, Rifles, Rye, Rome, Rose, Russia, Salt, Sardinia, Sardines, Sculpture, Sewing Machines, etc., and about 1,500 others. With us this Cyclopædia is a necessary companion—a *vade mecum*—consulted daily, and almost hourly. We would be glad to see it in every family. A few more may, perhaps, yet get it through our premium offers. See page 122.

Coffee Humbugs.—We advise our readers to give a wide berth to "Illinois Coffee," "Australian Coffee," "Japan Coffee," etc. We have had samples of several of these, and find them to be Okra, Virginia or chick peas, chickory, etc., seeds of which are abundant. ☞Will Mr. Huffman please make us *some* return for the $1.06 we sent him through a friend some time ago? We did expect he would send us at least a few seeds of his Australian coffee, such as it is, just to exhibit along side of the chick peas, (the same thing,) which we raised in our own garden last year.

Tobacco Seed.—Many inquirers in regard to tobacco seed will find an answer in the article on tobacco in the March *Agriculturist*. Where tobacco has not been raised extensively it is impossible to tell what kind is best. The "Conn. Seed leaf" matures in 2 months from transplanting, and has a broad fine leaf and mild good flavor; when raised on good soil it burns very white, has a good color, and sells for a good price.

Cotton in Kansas.—A subscriber in California Township, Coffey County, Kansas, writes that a lady residing in that County raised 120 lbs. of cotton last season, and worked the whole of it into cloth for the family, adding wool to a portion of it.

Okra.—This plant is not so generally known as it should be. The green seed capsules make an excellent nourishing soup, which we would not like to be without during the Summer. The plant is very easily grown; it may be sown in drills in the open ground, in April or May, and the plants thinned out to a foot or so apart. The earlier the seed can be started in the garden, or in a hot-bed, the sooner will the pods be ready for cooking. We have already published in the *Agriculturist* directions for making the soup. The green pods or capsules are boiled with meat juices, the same as for other vegetable soups. ("Mary," writing from Wayland, says that having lived many years at the South, they learned to cook okra the same as asparagus. The pods would need to be very young and tender. She also says its seeds, when ripe, make good coffee.)

Boiling Potatoes.—Whether it is best to put them into hot or cold water, was referred to us for decision, some time ago. After several trials, we cannot discover that it makes much difference; we give preference to putting them in cold water, to heat up with it.

Lice in Hen-houses.—P. Thomas, Jefferson Co., Ky. Thoroughly white wash the infested houses in every part. Lice and other insects have a great aversion to lime. Dust nests with dry lime or wood ashes, and have dry ashes for fowls to dust themselves in.

Top Dressing for Grass Lands.—"Robert," Northern New-York. It would have been better, perhaps, if you had applied the manure last Fall. But, if neglected then, don't let it slip this Spring. Perhaps the ground is yet frozen with you, in St. Lawrence, if so, it is easy to get into the meadows with an ox-sled. Or, if the frost is out, perhaps you can use a wide-wheeled cart, scattering the manure from the tail end, as the team moves slowly along. When the manure is used up, finish the rest with ashes, and see which gives the best results.

A Cheaply Grown Early Salad.—Take long boxes, about three inches deep, 4 to 6 inches or more wide, and of any length. Fill them with good friable garden soil; press it down, and sow upon the surface, English mustard, and curled cress, (pepper-grass;) and simply press the seed *upon* the soil with a board. Keep the boxes in any warm corner, in the house, in a light cellar, or in the green-house or hot-bed if you have either. The seed will spring up quickly, and as soon as the rough leaves begin to appear, the cutting may be commenced. It is good upon bread and butter, or may be used with vinegar, etc. By thus leaving the seeds upon the surface, and pressing the soil smooth, the leaves are kept clean. The soil needs to be kept moist by an occasional careful addition of water. A house-grown supply may be easily kept up all Winter and through early Spring. [F. Otto, for *American Agriculturist.*]

Peas with Potatoes.—Early peas sown in potato rows, will afford good picking for the table, and be out of the way before interfering much with the potato tops. (We speak from experience.) This is for good garden soil, rich enough to bear two crops.

Corn in Hills or Drills?—"Waterville, Me.," and many others. Where land is cheaper than labor, hills may be best, as more of the work can be done when the plow or cultivator is run both ways. But the largest yield can be obtained from drills. Five or six separate stalks, along 3 or 3½ feet of a drill, will give more ears than four stalks crowded into a hill. We prefer planting in 2 to 2½ feet drills, the kernels 3 to 4 inches apart, and after the stalks are safely and well started, to cut out the weaker ones, leaving them 6 to 10 inches apart, according to the variety of corn and size of stalks.

Skirving's Improved Turnips.—S. E. Fales, Sec. of Farmers' Club, North Wrentham, Mass., says he sowed some of this variety last season, and obtained specimens weighing 9 lbs., as smooth, handsome turnips as he ever saw. At a meeting of the Club they were pronounced the finest appearing turnips of the year. But up to Feb. 3, a variety called the Peruvian were best for the table.—Mr. F. received from the Patent Office a parcel of seed labeled "Lupius, from Egypt," which proved to be a common wild plant abundant in the woods along side of those growing from the seed received from Washington—a hint to the new Secretary, whoever he is to be. Another plant may be derived from the fact that seed of a wonderfully fine tobacco, with a jaw-breaking name, sent out to Connecticut from the Patent Office, proved on trial to be the common *Mullein*. The "Dutch Horn Carrot" from the same source proved good.

Leather Chips are slow in their action, but gradually decompose and afford a valuable manure. They contain enough of value to make them worth at a lowest estimate $4 a tun, and cart a mile or two, although so slowly available. Their decomposition may be quickened by composting with ashes and lime.

The Old Baskets can this month be turned to better account than for kindling wood. Fill a basket with good garden soil, and plant in it seeds of squashes or cucumbers. Keep it in a moderately warm place, with an occasional watering, and when the garden

is ready for planting, set the basket directly in the soil. The vines, already well started, will continue to flourish, and produce a crop several weeks ahead of the seed sown in the open ground at first. Potatoes, peas, etc., may be started in the same way. The roots readily find outlets through the sides of the basket into the surrounding soil.

To Keep Bugs from Melon Vines, etc.—A Good Plan.—G. Roys, Hartford Co., Conn., says the cheapest and most effectual remedy for the striped bug, is to cover the plants with cotton, thus: Take the common cotton batting, separate it into very thin layers, and spread over the plants as soon as they appear, putting a little dirt on each corner to prevent the wind from blowing it off. He has tried it for several years with entire success. The plants may attain considerable size before removing the cotton, which stretches as they grow. If thinly spread, the cotton does not interfere with light and moisture, while it entangles the insects.

Watermelons Change with the Soil.—I have planted seeds from *the same melon* on two kinds of soil, with the following results: Those on sandy soil, moderately rich, produced melons of large size and the finest flavor; while those planted on rich, loamy soil, turned out only poor, dry, spongy fruit, of small size.

No Seeds of that Big Pumpkin.—A large number are inquiring, by letter and otherwise, for a few seeds of that big pumpkin recently on exhibition here. As usual with such large specimens, it contained very few seeds—only 19 perfect ones all told—and these were spoken for months ago.

Rhubarb Good for Drying.—H. C. Smith, Vermillion Co., Ill., writes: "Among all the good things justly said in the *Agriculturist*, in favor of Rhubarb or Pie Plants, I have not seen it stated that when dried it is as good a substitute as dried apples for green rhubard—in fact, I like the dried rhubarb better than the green for pies. To dry, cut it in inch-long pieces, and spread it in the sun, the same as apples."

Rhubarb in Winter.—On February 15th we received from J. C. Thompson of Richmond Co., Staten Island, stalks of rhubarb 18 inches long, of a beautiful pink color, which cooked crisp and tender. They were grown in a dark but warm cellar, by merely placing the roots in boxes of earth in the Fall, setting them in the cellar, and watering occasionally. With a very little trouble some of the surplus roots of the garden, or crowns taken from large plants will furnish a considerable supply during Winter.

Get a supply of good Strawberries.—The premiums offered on p. 128 will enable many of our readers to secure, without expense, a supply of plants which will yield them large, luscious berries in abundance for another year. And what is more desirable in the garden, or rather on the table, than plenty of strawberries of the best kind, many times larger, more beautiful, and every way better than the wildlings, that cost more to pick them than they are worth. As already remarked, a few plants can be rapidly multiplied under favorable treatment. Half a dozen parcels of 25 plants each, can be multiplied this year, so as to supply a neighborhood next Spring. Suppose our subscribers at different points make up a club of four to seven subscribers extra, and secure seventy-five to one hundred plants, (or 105,) free of charge, and distribute them around. We doubt not they will feel repaid, and that next year we shall have in every place where this is accomplished, at least a goodly number of new subscribers—and plenty of old ones who *know* what good strawberries are.

The Poppy is Hardy.—We had taken for granted that the different varieties of the Poppy (*Papaver Somniferum,*) would be killed during Winter, if sown in Autumn; but we have direct evidence to the contrary. On going over the ground where the two kinds of poppy seed in our distribution list (Nos. 203-4) were grown, we find that where the seed dropped last Autumn, and came up, the plants are as fresh and green to-day (March 12) as a grass plot in the middle of May. This is in the open field, exposed to snow and frost, and the snow is just melting off from them.

Gladiolus and Japan Lilies.—Mary Favor, Winnebago Co., Ill. Bulbs of both the above should be planted in Spring. They are advertised in this papers. The cost varies with the beauty and the rarity, from 25c.@75c., and even up to $2 each for gladiolus bulbs, and 50c. to $1 for Japan lilies.

Mexican or Madeira Vine.—A Hartford correspondent of the *American Agriculturist*, writes that this is one of the best annual climbers for covering trellises, arbors, etc. It is grown from a tuber like the potato, to be planted as soon as the ground is warm. In a rich strong soil the vigor of its growth is very remarkable, hardy, climbing a cord to the hight of 40 feet. The leaves are broad, fleshy, light green, and very glossy; they are set close upon the vine, and about the time the vine approaches its full growth, branches are thrown out at each leaf which soon flower, and the whole plant becomes covered with pendent spikes of delicate and fragrant white flowers. It will not bear frost. In good soil the yield of tubers is very large. The botanic name is *Bowsingaultia basselloides.*

Picking Grapes at Christmas.—F. S. Vaslet, of Napa County, Cal., writes us that he has fresh picked grapes on his table last Christmas, and that he left some on the vines much later. He thinks they were better than if picked as soon as ripe in September. Cloths tied loosely over the clusters kept off birds.

Six Grapes for a Cold Grapery.—B. Ayres, Rock Spring, Pa., asks for the best six *native* grapes for a cold grapery, and also for six foreign grapes, for lat. 41°–800 feet above tide level. Answer.—So far as we know, *native* grapes have not attained their full perfection, under glass as a general thing. Perhaps the following would be as good a selection as any: Diana, Delaware, Herbemont, and Anna, (or Union Village, or Catawba). To Kalon, and Union Village, we have seen bearing freely under glass, but the fruit was of poor flavor. Native grapes usually have thicker skins and a harder pulp when ripened under glass, than in open ground, though they flourish well. For six foreign grapes a good selection would be: 2 of Black Hamburg, and 1 each of Grizzly Frontignan, Royal Muscadine, White Sweetwater and Zinfidel.

Budding Shoots kept in Vials.—H. A. French, Eaton Co., Mich., says that shoots for budding have been kept 3 weeks corked up in a vial with a few drops of water, and when inserted nearly all lived. Grafts could doubtless be preserved a long time in the same manner, by keeping them in a moderately cool place.

Transplanting Evergreens from the Forest.—D. Dunn, jr., Washington Co., Pa. This is a somewhat uncertain operation. The roots, especially of white pine, have few fibers unless grown in a light good soil. The *best* way is to begin with forest or pasture trees early this Spring, digging about them and cutting off the tap-root. Fill up fine soil for new root fibers, and then leave until May of next year, when they may be transplanted with fair success, if the roots be kept from sun and dry air by covering during their removal.

Urbaniste Pear.—T. M. B., writing from the pear-growing region near Boston, Mass., takes us to task for omitting the Urbaniste in the list of pears for an orchard, published on page 36 of *February Agriculturist.* Our only reason for omitting this really good pear is that it comes late into bearing—several years after some other varieties have been yielding regular crops.

Wash for Fruit Trees.—Solomon Robinson, Worcester Co., Mass., uses the following wash on his fruit trees with good effect. Put a pailful of water in a tub, and stir in 3 quarts fresh cow manure, 1 quart soft soap, 2 quarts sifted wood ashes, and add urine enough to make the mixture of the consistence of white wash. Apply this to the trunks and limbs of the trees early in June, with an old broom. The manure and ashes form a coating which each rain gradually removes, leaving a clean glossy bark, and also carrying fertility into the soil.

Grafting the Wild Apple, Plum, etc.—Ernest Eggert, Clayton Co., Iowa. The wild apple tree (native crab,) can be grafted in the branches, but it is better to bud it near the ground, while small, with some approved sort of large apples. The wild plum should always be budded, and it is safest to bud the cherry. It is difficult to make the common cherry take upon the stalk of the black or very small red sort. It will succeed on the mazzard or heart-shaped wild kinds.

Varieties of Apples for Suffolk Co., L. I.—H. L.: Consult the extensive list of proved sorts published on pages 110 and 143 (April and May,) of the last volume of the *Agriculturist*, and make selections accordingly. Those lists were full, and good for different parts of the country. (Those not having them can obtain, post-paid, copies at 10 cents each. The three numbers, April, May and June, give more full information in regard to the best kinds of apples for different parts of the country, than has been yet published anywhere else. Any one intending to plant an orchard can well invest 30 cents in those three papers.)

Germinating Locust Seed.—A. F. Gillett, Poweshiek Co., Iowa, says Locust Seed must be sprouted with hot water, before it will germinate freely. Pour on boiling water, let it stand until cold, pick out all which have burst their shells, and pour on more water, sorting out as before; mix with dry sand and sow.

Renewing and Preserving Peach Trees.—J. C. Thompson of Staten Island, recommends cutting peach trees off two feet from the ground, and covering the ends of the stumps, or large limbs, with cement. A healthy tree makes a great growth of young wood, easily controlled by summer pruning, and ready to bear the next year, not liable to break by winds, and easily supported if heavily loaded with fruit, which is also within easy reach. Mr. T. has also practised, for several years, applying about a handful of flower of sulphur about the base of peach trees. The base of the trunk being laid bare, and the worms removed, the sulphur is placed about it and the earth returned. This is done once in two years.

Crops in Young Orchards.—"A New Subscriber" asks what crop to plant on ground where a young orchard has just been set out.... Roots of some kind are best—carrots, rutabagas, or mangel wurzels. They may not be planted nearer the trees than about six feet, but the ground around the trees should be kept tilled just as if it was all planted, but not so deep as to disturb the roots of the trees.

Orchard Grass.—T. Conner, Chittenden Co., Vt. Most of our common grasses are weeds when growing *out of place.* Orchard grass (*Dactylis glomerata*) may be harder to exterminate than some other kinds of grass, but in our experience by no means so bad a weed as Quack or couch grass, (Triticum repens). Clean tillage of hoed crops, and clean seed for grain, will probably remedy your difficulty.

Blue Grass—Information Wanted.—J. T. Hayman, (P. M. at Kane P. O.,) of Campbell Co., Ky., asks that some one thoroughly acquainted with the Blue-grass region of Kentucky, would give definite details in regard to the culture of this grass—its value and use, the soil, mode of sowing, curing, etc. Such information would interest many others.

Sprouting Sorghum Seed before Planting.—A subscriber of the *Agriculturist* in Winnebago Co., Ill., writes that a neighbor who is an experienced cultivator of the Sorghum Sugar Cane, recommends to "soak the seed until it sprouts, before putting it in the ground; if this be done it comes up quickly and gets the start of weeds." (This, if properly done, may be a useful plan. The Sorghum seed, when over dry, starts rather slowly, and the young shoots, which resembles those of oats, make but a feeble growth for some time, and on this account are more difficult to hoe and weed out than corn. If previously soaked, as above recommended, the seed should be kept only moist, and not in water; if not spread out somewhat thin it would heat; and the sprouting should only be carried to the swelling of the seed and just breaking of the shell, for there would be danger of injuring the germ in sowing, if allowed to start out beyond the shell.—Ed.)

Long *versus* Short Parsneps.—On the score of production, it is reasonable to suppose that long parsneps and carrots are preferable to the short round varieties; the tops of those a foot or more long occupy no more space than those running down only three to six inches. We have another experiment in favor of long parsneps, especially when to be left in the ground over Winter, as they should be if desired in tender condition for the Spring table. On a plot of short round parsneps, which we raised last season, we find this Spring that the roots are all heaved out upon the surface and nearly destroyed by freezing—a thing that, with us, has never happened to the long rooted kinds in the same ground.

Raising and Keeping Celery.—S. Greenwood, Shelby Co., Iowa. This is very easy and pays for the trouble, in every garden. The field culture was fully described last month. The following is our method. Sow the seed thickly in a small rich bed of soil the last of April, or first of May. When the plants have leaves 3 or 4 inches long transplant to a trench made thus: A week or two before transplanting, dig one or more trenches a foot wide and 18 inches deep; put into the bottom 10 inches of a mixture of half good soil and half good manure, or the best you have, covering with 2 inches of good soil. Set a row of plants in this about 5 inches apart; water frequently, and keep shaded from

the mid-day sun with boards, for three or four days or until they start into growth. As they grow, hoe frequently, gradually bringing in a little soil around the stems, holding them together so that no earth shall fall among them. Continue to draw the soil around them until the approach of frost, when with a good growth you may have an embankment a foot high, and good stems 15 to 18 inches long. Some take them up before frost and put into boxes or barrels of earth in the cellar. We leave them in the garden, covered with earth enough to keep frost from the lower part of the plants, and with an ax or mattock cut off the frozen ground and take out the plants as wanted for the table. By the above plan we have never failed to secure a full supply of first-rate celery for Winter and Spring. The blanched white tender stems, washed clean, and eaten raw with a little salt, are a most excellent relish.

Earthing up Celery.—"Runnymede" of Cottage Farm, Dutchess Co., N. Y., says he knows no better way of blanching celery than to set the plants on level soil, and only earth up, one row at a time, as wanted for use in the Fall. It blanches sufficiently in 5 to 10 days, and without the rust common to that which has been bleaching for months.

Lima Beans, Early.—To secure an early crop of this delicious but late maturing bean, cut numerous bits of sod 2½ or 3 inches square, set them above a good bed of manure in a hot-bed, and plant a bean, eye down, in each, cover with soil to the depth of an inch. Transplant them in May, lifting the sods without breaking them, and put two or three to a pole in a warm sheltered spot. Pinch off the top of the vine when about 5 feet high to still further promote early maturity.

Amount of Lime on Wheat—Correction.—Mr. Reynolds writes that in the first paragraph of the "Spring Wheat Article," page 46, he intended to recommend *ten* bushels of lime, instead of two. The two words resemble each other in writing.

Weeds and Potato Rot.—O. W. True, Franklin Co., Me., referring to Delaware farmer's note on page 70 (*March Agriculturist*,) says that during the prevalence of the potato rot in Maine, he has many times noticed that in fields affected, the disease was always more destructive where grass and weeds were abundant, than in the clean ground of the same field; sometimes the former were left undug, while the clean plots yielded 150 to 250 bushels per acre. Early deep planting, with clean culture, always does best.

The Elder Sap-Spouts, noted on page 63, should have been credited to S. Hatton, Warren Co., O.

Catching Moles.—John H. Sharts, of Indianapolis, writes that moles confine their travels mainly to a short period after sunrise, then just after mid-day, and again just before sun-down, and that their location can then be easily ascertained by the movement of the ground. He closes the new made track just behind them with the heel of the boot to stop their retreat, and then catches the marauders. This may do if there be but few of them, and one has time to watch their motions. (We have recently received several mole traps from different subscribers, at least one of which appears to be very simple and effective. It is a cheap home-made apparatus, and will be sketched and described in the *Agriculturist* for May.)

Sourness in Soils.—C. J. C., of Summit Co., Ohio, asks "If alkalies neutralize acidity in soils, why is it that when timber has been burned, and the ashes left, moss and sorrel are the first things to grow?".... The use of the term sour and sweet, in regard to soils, conveys a somewhat false idea. True, vegetable acids abound in wet soils. It would require an immense quantity of alkali to neutralize the vegetable acids on a peaty soil, for they constitute a large part of its bulk. Sorrel does not grow on "sour" soils because they are sour, but because it finds congenial conditions of growth. A soil may be half vegetable acids, and yet not sour. We should say wet and dry instead of sour and sweet. Nothing *sweetens* a soil like letting the air into it by under-drains: no amount of alkali will "sweeten" a wet soil.

Lime on heavy, cold Land.—H., West Bridgewater, Mass., wishes to know what to do with a piece of cold wet swale land, with a mucky soil, and below a clay hard pan; it has recently been drained; heaves badly by frost; and bakes by the sun. He has no yard manure to spare. Put on at least 100 bushels of slaked oyster shell lime to the acre. Spread it evenly and work it in on the surface with a coulter-harrow or light plow. After a week or ten days harrow and sow grass seed. This is supposing the land to be well drained, which is the first or most important thing.

Sawdust and Fine Shavings in Manure.—A subscriber in Farrington, N. H., says he finds both sawdust and fine shavings very useful when mixed with manure to absorb the liquid, or rather used as bedding for cows and horses. Sawdust seems to operate better than even the fine shavings from a planing mill. There is no doubt that these and all other organic materials not only act usefully in retaining liquid manure, but they also, of themselves, as they decay in the soil, furnish some organic elements for nourishment of plants.

Cart vs. Wagon.—"C. R." asks "which is best?" For many purposes, the one-horse or the two-ox cart is best. The wheel being made broad, they can pass over soft ground with a load better than narrow wagon wheels. So, too, the cart is more convenient for dumping loads of sand, gravel, manure, etc.—the entire mass being easily tilted off at once. A cart is also more convenient for turning about. But then, the cart requires a heavier horse than the wagon, and is not so convenient for drawing of loads, stalks, hay, etc. A careless man will not balance the load properly to save straining a team. For stumpy or stony land, the cart may well come into more frequent use. The kind of each man's work will help him decide the question.

Farmer's High School of Pennsylvania.—We are informed by Dr. Pugh, President of this Institution, that the 4th Annual Session of ten months has just opened under very favorable auspices, notwithstanding the disturbed state of the country. Nearly ninety students have already entered, but there are a few more vacancies yet, which he desires to be filled. The course of study extends through four years, and is mainly devoted to science and the industrial arts, in connection with agricultural practice. The cost for board, room rent, washing, and tuition is only $100 per session. Persons wishing further information, should address Dr. E. Pugh, Farm School P. O., Penn.

The Association of Breeders of Thorough-bred Neat Stock, held its third annual meeting at Hartford, March 5. The President, Paoli Lathrop in the Chair. After reading and accepting reports of the Secretary and Treasurer, which latter showed $233 in money on hand, with some liabilities for advertising, etc., the Association elected officers for the ensuing year, as follows: *President*, S. W. Buffum, Winchester, N. H.; *Vice Presidents*, R. Linsley, Meriden; D. Buck, Poquonnock; Milo J. Smith, Northampton, Mass.; C. M. Pond, Hartford; H. H. Peters, Southbury, Mass.; *Secretary and Treasurer*, Henry A. Dyer, Brooklyn, Conn. The Committees on Pedigrees (three for each of the four principal thorough-bred races of cattle,) were re-elected, and the Publication Committee also re-appointed, and authorized to proceed with the publication of a herd-book for each breed, to include the pedigrees passed upon by the Pedigree Committees. The Pedigree Committees reported having passed upon and affirmed 206 Short-horn, 197 Devon, and 212 Ayrshire pedigrees—each committee having still a number under consideration, and having rejected a considerable number. The Com. on Jerseys made no report of pedigrees. The membership fee was reduced to $1. Pedigrees are investigated, and if found perfect, are published in the Society's herd-books, at a charge of 50 cents each. The Association has members among the prominent stock-breeders of the Eastern and Middle States and Canada, and some at the West; is flourishing, and seems likely to do much good. The Secretary will furnish other information.

Royal Hort. Society of England—A Hint to New-Yorkers.—The Annual Report of the above Society shows it to be in a highly prosperous condition. The number of Fellows, or Members, on Jan. 1st, was 2,174. These contribute from $3 to $20 each, the lowest annual dues being one guinea, ($5). A considerable number commute for a period of years, or for life, paying 20 to 50 guineas. For 8 months prior to Jan. 1, the receipts from members alone amounted to nearly $44,000. The old Garden at Chiswick were found to be badly located for the convenience of the present public, and the new Garden at Kensington has proved a valuable enterprise. On the death of the late President, the Prince Consort, the widowed Queen was consulted as to a successor. She stated that were it compatible with her position she would gladly occupy the chair. She nominated the Duke of Buccleuch who was at once unanimously elected President. Prof. Lindley, the eminent botanist, continues Secretary. Our horticulturists in and around New-York, will find it worth their while to study up the history of the London Society. It is high time that something more effective were done towards establishing in the Metropolitan City of this Continent a great central Horticultural Society, with its gardens, etc. We have all the facilities for such an enterprise, could they be properly brought into requisition. A *leader* is wanted.

Removal.—The Agricultural Warehouse of Messrs. Haines & Pell, (late Tredwell & Pell,) destroyed by the recent Fulton-st. fire has been reopened at 27 Courtlandt-st. We are glad to learn they were insured.

Rec Books—Jenny Corn—Keystone Club.—C. Hoffman, Dauphin Co., Pa. Langstroth's Work on Bees is a good scientific book, costing $1 25, post-paid. Quinby's is also a practical work, costing $1, post-paid. We would not like to be without both of them. The "Jenny Corn" we did not advertise because we did not know enough of it to warrant us in placing it before our readers, though offered pay for doing so. The Keystone Club we know nothing against; it is no individual agency for collecting subscriptions for the commission allowed by publishers, we believe.

A Very Good Little Book is one entitled "Mistakes of Educated Men," and of *others*, might well have been added. This was first written as an address to young men just going forth from College to active life, and points out clearly and convincingly, a few errors to be avoided, and plans of labor to be adopted, in order to success. The hints given are important, and we advise every father to read the book himself, (it will only require an hour), and then put a neat copy into the hands of each one of his sons, no matter what is to be their calling. The author, John S. Hart, was for 20 years Principal of the excellent Philadelphia High School, and the hints given in this book are the result of his experience and observation after training, and following the subsequent career, of more than 4000 young men. (Price, post-paid, in neat binding, 50 cents.) J. C. Garrigues, Philadelphia. We add it to our book list on page 126.)

Childrens' Feet.—"X," of Middlesex Co., Conn., advises parents to see to it that childrens' feet are kept warm at night, and recommends that this be looked to an hour after retiring, and if the feet be cold, a bottle of hot water or a warmed brick be applied. If this be attended to, many of the "mysterious dispensations of Providence," in the removal of children, will be averted. If children are restricted to light suppers, say only *a moderate* supply of bread and milk, or milk and rice, or hasty pudding, they will be less troubled with cold feet and restless brain. A load of food in the stomach withdraws blood from the rest of the body, and leaves the lower extremities cold, while it also disturbs the brain.

Merchant Farmers.—D. S. W., of Philadelphia, inquires: "Do you suppose a man of industry brought up to business in the City, and of course without any practical knowledge of farming, but having sufficient means to purchase and stock a farm of say 50 acres, could make both ends meet by depending on hired help until he acquired the necessary knowledge?".... Yes, with good help, and making no "improvements" for a year or two. A good business man will make more money on a farm than a born and bred farmer *without* business habits.

For Stopping Leaks in Roofs.—A correspondent recommends the following: "Take four pounds rosin, one pint linseed oil, and one ounce red lead, simmer together slowly while hot. We have no doubt it is an excellent recipe, and the cement may be applied to other purposes of similar character.

"Rev. E. A. Wilson" a Humbug.—We supposed we had exposed the person advertising over this name sufficiently to put all readers of the *Agriculturist*, at least, on their guard. But our newer readers may need a new caution, at least we so judge from sever al recent letters of inquiry. It may therefore be said in brief, that we have never yet been able to find "Rev. E. A. Wilson." He formerly claimed to have been a preacher in the "New-Haven Conference." This falsehood we nailed by reminding our readers that Methodists themselves never heard of any "New-Haven Conference." He now substitutes the "New-England Conference." His own advertisements in the N. Y. Tribune, and Times, he quotes in his pamphlet as if they were editorial endorsements from those papers. (They deserve this for even inserting his advertisements.) This *so-called* Rev. E. A. Wilson, (like all the rest of the class) pretends to great benevolence, and a desire to benefit the afflicted without charge. He sends a "prescription" it is true, but while by specious statements he almost or quite convinces the nervous suffering that his medicine will be their salvation, he is very careful to inform them that the medicine is very costly and difficult to get in a pure state, and that the safest way is to send him (the "Rev. E. A. Wilson,") *two* dollars, and fifteen cents more for postage, and get the genuine medicine. This is the practice of all of these "retired Physicians," retired clergymen, and other benevolent humbugs. That they deceive many, is evident, as they continue to expend very large sums in advertising.

Farm-House Plans.

The accompanying plan (Fig. 1.) of the ground floor of a farm house is sent to the *American Agriculturist* by a subscriber in Williams Co., Ohio, who writes, "I propose to adopt the within plan if I can get no better, and ask for any improvement on this, or other plan which will suit the location." We present a plan (Fig. 2) which we think to be an improvement upon it.

Fig. 1.—PLAN OF MAIN OR GROUND FLOOR.

(Explanations applicable to both plans—*a*, Front entry; *b*, Sitting or dining room; *c*, Family bedroom; *D*, outside doors, *d*, inside doors; *e*, Parlor; *f*, Parlor bedroom; *g*, Kitchen; *h*, Pantry; *i*, Closets; *K*, Veranda; *l*, Linen closet; *o*, Oven; *R*, Roof; *S*, Shed; *w*, Windows.)

In the plan (fig. 1) sent for criticism, 1st, there is in proportion a great deal of outside wall; 2nd, the kitchen is far from the dining room; 3d, the pantry is made a passage way; 4th, the 5 outside doors all open into principal rooms; 5th, there are no closets; and 6th, the rooms are generally too small. In fig. 2 we remedy the first objec-

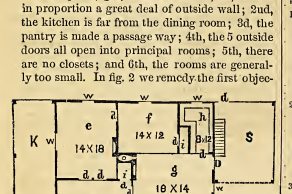


Fig. 2—PLAN OF MAIN OR GROUND FLOOR.

tion by making the house square; the 2nd and 3d by a different arrangement; the 4th by a front entry, and only 2 outside doors; the 5th, by putting a good closet in every room but the parlor; and the 6th by economy in the arrangement of rooms, only adding 12 feet horizontal measure to

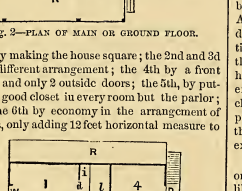

Fig. 3—PLAN OF SECOND FLOOR.

(1 and 2, are 2nd Story bed-rooms; 3, Maid's room; 4, Men's room, with entrance, *D*, by outside stairs.)

the outer walls. The bedroom does not open into the dining-room or into the kitchen, as one never should do. From the front door you pass directly either into the sitting room, kitchen, or bedroom, down cellar or upstairs. The pantry is in the coolest corner of the house. Folding doors almost make one large room of the parlor and sitting room, and a double window makes the kitchen very light. A large Veranda, 10 feet wide goes round two sides of the house; it is a great and cheap luxury, especially in hot weather. The windows on the west, which if they could be so arranged should be the south side, ought to reach the floor. We give also a plan of the 2d floor for a story-and-a-half house—sufficiently explained by the references. We have not "figured upon it," but judge that the plan we propose throwing out the Veranda, would be the cheaper of the two.

The Patent Office Agricultural Department—Where the Money Goes.

We have more than once taken occasion to show up the sham affair at Washington, kept up under the specious name of an Agricultural Department. Here is a specimen of the way the money is expended—the following figures include a period of less than seven months, viz.: from July 1, 1861, to Jan. 23, 1862, not including the large sum paid for printing the "Reports." We take the Tribune's figures, professedly copied from the books at the Patent-office:

1. *Seeds*: To Vilmorin, Andrieux & Cie., Paris, for seeds ordered by Mr. Clemens, $14,998 94; to Paschall Morris, Philadelphia, for seeds, $10,746; also to F. Morris, $83 for 50 bushels of Mediterranean wheat, and $40 for 100 bushels of barley; to Peter Gorman, $85 for 50 bushels of Tappahannock wheat; to C. Edwards Lester, $50 for 50 ounces tomato seed; to Chas. A. Leas, $75 27 for box of Wuigan (?); for seed bags, $1,467 53; for filling bags with seeds, $250 31; for freight, $373 79. Total.....$28,105 84
2. *Salaries*,—Under general head of "Salaries," $11,471 49, to which add: Paid D. J. Browne, for services in Europe, $1,500 (*what* service?); David A. Wells, for 50 pages of Report, $300; Samuel J. Parker, for article on grapes, $70; Louis Baker, for article on palm sugar, $15; Louis Schade, for article on lupine, $11 50; for copying Report, $432 98; for drawing, $15; for cutting grass and keeping the yard around the Patent-office, $284 70. Total.....$13,960 95
3. *Sundries*.—Books and papers, $22; paste, oil chairs, etc., $130 41; use of horse, $328 88; covering Reports, $73 25; stationary, $1,408 98(?); rent, $50. Total.$1,922 52
4. Propagating garden $2,348 77
Total, 18 months and 3 weeks $46,534 08

We have not arrayed the above figures to show the total as anything frightful. Ten or twenty times forty-six thousand dollars would be cheerfully accorded to the Department of Agriculture, if *well* expended in collecting and disseminating useful statistics and other information respecting the great industrial prospects of the country. But can any one tell us what we have, or shall have, to show for the $46,534 08 expended as above—save, perhaps, the $2,548 charged to the Propagating Garden? The propagating and experimental gardens were the only redeeming feature we found after much examination of the concern at Washington.

Take the *seed* expenses, for example. Can any one report anything good that has come, or is likely to come, of the twenty-eight thousand dollars expended, or of the similar sum expended annually, for years past? We hesitate not to assert, that there were, during the last Summer alone, more plants of beautiful flowers, and more fields of Chinese sugar cane, of improved corn, oats, etc., growing from seeds sent free from the office of the *American Agriculturist*, than from all the seeds distributed from the Government Seed Store at Washington in five years past. (Government derived over $2,700 *postage* from seeds we sent out last year.) And at an expense of less than $3,000, we shall this year distribute *more* parcels of seeds, scatter them among ten times as many persons, and secure wider and better results in the future, than will come of the $28,000 expended at the Patent-office for seeds. We say further, that the three chapters of Reports on Apples, gathered by the *Agriculturist* last Summer, offered more *useful* statistical information than will be found in any Annual Report of the Agricultural Department during several years past. Again, the Crop Reports to be published in the *Agriculturist* the coming Summer, will be worth more to the farming interest of the country than any year's operations yet performed at the Government establishment. By the way, as the *design* of the Patent-office seed distribution is to gather and distribute rare and valuable seeds from *foreign* countries, we should like to know what *kind* of seeds were furnished by the Philadelphia Seedsman, to the amount of eleven thousand dollars.

So much for the past and present. As a new system—a "Bureau of Agriculture,"—is now to be established, we trust some man will be appointed at the head of it who shall be able to strike out upon a new track. Let him expend less money in distributing *common* seeds, and more in getting Statistics upon the amount and condition of the growing crops, the different modes of cultivation, the kinds of grain, fruits, etc., best adapted to the several sections of the country. Let new varieties of seeds, cuttings, etc., gathered in other countries, be first *tried* on experimental plots at a few points, before large purchases are made and the seeds scattered at random over the country, often to prove utterly worthless, if not an actual pest, as they have sometimes proved. In these, and other ways, the new Agricultural Bureau may prove of use.

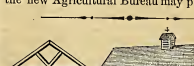

Fig. 1. Fig. 2.

Hints on Tobacco Culture....No. II.

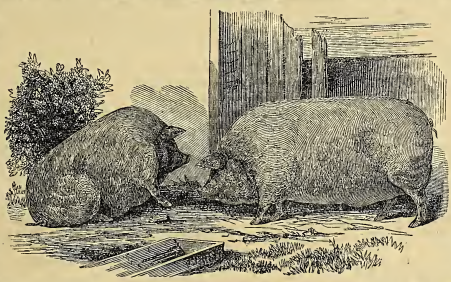
Light, mellow, and deep sandy loams are best, if sufficiently enriched. Lime soils are considered bad, and heavy loams do not produce quite so fine a quality of tobacco, though perhaps larger crops. Spread on enough barn-yard manure, or compost of the best quality to make a crop of 80 to 100 bushels of shelled corn to the acre, and put it fully 7 inches under ground. On sward land, turn the sod flat, 10 inches deep, with a Michigan plow, then manure and plow it in deep, not disturbing the sod. The land must be plowed again in June.

The preseut may be as convenient a time as any to put up tobacco sheds, and we give figures and a description of the kind common in the Connecticut Valley. Figure 1 is a section showing the frame and poles on which the tobacco plants are suspended. Figure 2 shows the arrangements for ventilation. The building is framed 24 feet wide, the posts 16 feet high. On the sides, and through the middle, between the posts, are three tiers of scantlings, to which the boarding is nailed, which are placed so as to support the 12-foot of rails or poles on which the tobacco is hung—25 to 30 plants on a rail. In fastening on the outside boarding, about every third board is hung on hinges, making openings from top to bottom. Ventilators are placed in the shingled roof, at least one in every 48 feet. These "sheds" are set up some 18 inches from the ground, on brick or stone, and it is best to have shutters swung so as to close the opening all around. They have no floors, and are of indefinite length.

Where Did It Come From?

The following interesting experiment we have stated in an occasional agricultural address, and have perhaps already given it in the *American Agriculturist*, but it is worth repeating. Two hundred pounds of earth were dried in an oven and weighed, and afterwards put into a large earthenware vessel, and a willow tree weighing 5 lbs. planted therein. During five years the tree was watered with pure rain or distilled water; and to prevent any addition of earth or dust, the vessel was covered with a metal plate, perforated with holes so small as to admit air only. At the end of five years the tree was found to weigh 169¼ lbs. The annual crops of fallen leaves were not taken into account. The earth was then baked and weighed as at first, and had lost only 2 ounces. *Whence was derived the 164 lbs. of woody fiber, bark, roots, etc.?* They must have come to the plant from the atmosphere, and the rain water, through the medium of the leaves, roots, and bark. We see all around us similar examples. Yonder old field of ten acres has annually produced at least one ton per acre of grass, straw, grain, corn, etc., for a hundred years, or a thousand tons, (two million pounds!) of materials which have been carried off and consumed elsewhere, while perhaps the only addition to the field has been less than a quarter ton of seed. Yet the field has not sunk lower by reason of any loss of substance. Indeed it will weigh more to-day than before all this cropping, by nearly so much as the weight of the grass roots and black mold now in the soil. It has lost a little of soluble mineral matter that has been carried into the plants by the sap, and left there, either absorbed into the substance of the plants as constituents, or left there by the evaporation of the sap.

The truth is, soils do not "wear out." They are the machine in which plants are manufactured from air furnished materials. When the plants decay, or are burned, they return the matter to the air, which is the great storehouse of plant food. The skillful cultivator gathers a larger share of this plant material than others. The more skillful one not only gathers an annual supply in the form of crops, but he also secures an extra quantity which is stored in the soil as an additional stimulus or nourisher of the next crop. This he does by sowing clover, or seed of other plants which absorb large amounts of plant food in the form of leaves, stems, and roots; these he turns under, and holds them in store for another crop. His soil is thus increased in quantity, especially in organic elements which adapt it to the production of larger crops. In the absence of home-made yard manure, there is no better way to renovate old land, or to lighten heavy land, than to plow in green clover, or buckwheat, rye, millet, oats, etc. The green crops thus mixed with the soil answer several purposes. As they decay, they furnish richer stores of new food, which nourish and strengthen the growing plants, and prepare them to absorb more food from the air; by their decay they leave the soil open and porous, admitting more air and warmth into it, and drawing off water; and the mold formed by decaying vegetables, darkens the soil, making it absorb more of the sun's rays, and thus become warmer. Clover, by reason of its abundant leaves, and the large amount of nitrogen in its composition, is the best green crop to turn under. But where the soil is too poor to grow clover, other coarser crops, as buckwheat, may be first used to bring up the soil to the clover bearing point. Two or three crops of buckwheat may be grown and turned under in a season. Plaster of Paris is generally useful to start clover.—The first days of this month (April) should be improved in sowing clover seed upon the growing wheat and rye. Choose a still, cool morning, when the ground is opened with myriads of frost cracks; the seeds will drop into these, be well covered by the thawing soil, be warmed into active life by the spring sun, be shaded by the growing grain until rooted, and after harvest will afford considerable pasturage, and the next season good pasturage, mowing, or green manure.



Chester County Hogs.

Some notices of the qualities and doings of these hogs have appeared from time to time in past numbers of the *Agriculturist*, and many inquiries concerning them have been received. The accompanying sketch engraved from a photograph of two of them owned by Paschall Morris, exhibit the prominent points of the breed—if a distinct breed it may be called. To establish a breed a long succession of careful selections from the same family is required. That considerable care has been exercised with the Chester County hogs is evident; the only point of doubt is, whether this has been continued long enough to stamp indelibly the characteristics of the tribe upon all pure-bred animals. The frequent breeding of hogs, makes less time requisite, than for horses and neat cattle, which breed but once a year and require a longer time to arrive at maturity. From all accounts, it would seem that reasonable care has been taken for some twenty years past, and the present race, though scattered pretty well over the country, hold their own; and if not now entitled to the claim of a distinctive American Breed, they soon will be. We trust breeders will exercise great care to bring this about. They are supposed to have originated some thirty years ago, from a cross of an imported Bedfordshire boar with the best common stock of Chester County, Pa. All the notices of them that we have received or seen have been in their favor. If any one not prejudiced by other interests, has anything to say against them let us hear it.—The claims of the Chester County hogs for public favor are: good constitution, large size, length and depth of carcass, smallness of bone and offal, quiet habit, and well larded inside. The color is pure white, well coated with silky hair. Any black hairs, or the least variation from white is regarded as a mark of impurity.

Value of "Blood" in Animals.

It has often been shown in the columns of the *American Agriculturist* that, in the improvement of all kinds of domestic animals, very much depends upon securing the use of *well bred males*. This is pre-eminently true in the breeding of neat cattle, and with this class of stock we have the ability, over the whole country, to obtain the use of thorough-bred animals. A strange prejudice exists against acknowledging the fact, every day demonstrated, that grade, cross-blood, or "native" bulls, beget calves as likely to be bad as good, and upon which we can make no sort of calculation unless it be in the case of some old bulls. We sometimes, but rarely, find that a grade bull gets excellent stock with great uniformity. In this ability to propagate good qualities (not necessarily his own) he only shows the excellence of some strain of blood from which he is sprung. We do not know the fact, however, until his progeny are grown. The thorough-bred bull, on the contrary, marks *all* his calves after his breed and usually also after himself. Male animals give to their immediate offspring, with considerable uniformity, muscle, bone, spirit, and external characteristics; and in the thorough-bred races they impress other characteristics usually derived from the dam, particularly milking qualities. We all doubtless have knowledge of families of milkers of the old native stock in which, for generation after generation, the cows looked alike and milked alike; so much so that "Old Brindle's" heifer calf was sure to be raised, and we were almost morally certain that in the course of time all the old favorite's good qualities would be developed in her; the influence of the scrub bull, her sire, not being taken into account at all. Now-a-days, we see the progeny of Jersey and Ayrshire bulls with good, bad, and indifferent cows almost uniformly taking after the breed of their sires, in milking qualities as well as in characteristics logically expected from the sire.

We argue then, and urge the consideration upon our readers, that the most direct, feasible, economical, not to say the *only* available way for most of the farmers of this country to improve their stock is by the use of thorough-bred males. Evidently, an animal is not thorough-bred when he is only three-fourths or seven-eighths pure blood, yet he may be handsomer and every way a better animal than any thorough-bred in the neighborhood. Still, you can not be sure that his calves will be good; while even a very inferior looking thorough-bred bull is almost absolutely certain to get first class calves from grade cows.

Our breeders of thorough-bred cattle, of all the improved breeds, commit a great error in holding their bull calves at so high a price as to prevent sales, and finally, as is often done, making stags of them rather than sell them at a low price. If they would even give away the bull calves, which they do not wish to keep and which are not worth a *very high price*, on condi-

tion that they shall not be used upon thorough bred cows, and charge proportionately higher prices for the choicer calves of the herd, breeders would find it greatly to their advantage. In some such way the public must be brought to appreciate the value of blood.

Tim Bunker on Family Horses.

"In faith, she's dead as a herring, sir," said Patrick, as he came from milking, yesterday.

"Poor old crature, is she gone indade?" asked Bridget, the maid, as she lifted the corner of her apron, and wiped genuine tears from her eyes.

This was sad news, though I had been expecting it for several mornings, and not a very good preparation for breakfast which was already upon the table. I saw it was all over with the old mare, the mother of John's Blackhawk colts, and the faithful family beast of twenty-five years standing. She had been ailing for a fortnight, a little stiff in the joints at first, but nothing alarming considering her years. She had been serviceable up to that time, and though neither so strong nor so swift as in her younger years, was just as good for my purposes as a dozen years ago. When she began to refuse food, I resorted to the usual remedies, but soon saw that it was of no use. She died in her stall, on the fourth day after refusing food, full of years, and full of honors. I own that I set more store by her than any thing else that goes upon four legs. I had raised her, and ridden behind her to mill and to meeting, for over twenty years. Her disposition was a great deal more human than that of the common run of mankind. She knew her place and her business better. She was so completely under the control of my voice, that I never had occasion to strike her a blow. John lived upon her back almost, when he was a boy, and the women could drive her any where. She was the first horse John and Sally ever learned to drive, and she was associated in my mind with their childhood. It will go hard with John when he hears the news, down on the Potomac, for old Rose was the companion of all his boyish pleasures, until he was big enough to break colts. There is not a fish pond, or trout stream, within a dozen miles of home whither she has not carried him. He can hardly think of a pleasant spot, or a happy day in his childhood, a 'berrying with his school mates, or a 'visiting with his cousins, without recalling the nimble feet of old Rose.

It so happened that Sally and her husband were at home on a little visit yesterday, and it seemed to lighten the load a little, that we had children and children's children in the house, when there was so dark a shadow upon the barn. But it was rather a sad breakfast, even with these alleviations.

"She was just Sally's age, and—" remarked Mrs. Bunker, as she passed my cup of coffee, without being able to finish the sentence.

"What's the matter, grandma," asked little Timothy, who did not exactly understand the trembling lip, and the tears, that the spectacles did not hide.

"One of the earliest things I can remember," said Sally, "was a ride to mill, after old Rose, with you, father, and John. I couldn't have been more than four years old. I know John got to sleep before we got home, and you left him under the shed to take his nap out. You must not laugh at us, Josiah," directing her remarks, by way of apology, to her husband, "for our tears for old Rose. She was the mother of our Charley, you know

"A very remarkable beast, I have no doubt, from the impression she seems to have made upon those who knew her best," said Mr. Slocum, trying to enter into his wife's sympathies. "I have always thought horses approached nearer to man than any other domestic animal. The name of the horse recalls little Rose, in the Shady Side, who seems to have been so much afflicted at the sale of her father's horse, Pompey, as you are at the death of the family mare."

"Oh yes," said Sally, "I remember the passage, and it is one of the best in the book, where Mr. Vernon, the clergyman, had to sell his favorite horse out of sheer poverty.—'The children got bravely through the dinner; but afterwards, seeing her father look sadly out toward the empty stable, little Rose climbed his knee, and whispered, 'Never mind, dear papa, we shall see Pompey again—in heaven,' she was about to say,—but suddenly recollecting, she added, 'Oh no! he has no soul, has he? poor dear Pompey!' and the tears rained fast through her chubby fingers, with which she tried to hide them from papa.'"

"I do not altogether sympathize with the theology that takes it for granted that there is no hereafter for brutes," said Mr. Slocum.

"I should like to think so," said Sally, "now that old Rose is dead, but I can not see what place there is for animals in a spiritual world."

"I believe the Bible has not much to say on that point," said Mrs. Bunker hopefully.

"Very true," said Mr. Slocum; "and it is worthy of notice, that the most pointed thing it does say against their immortality, Solomon puts into the mouth of an infidel arguing that 'man hath no pre-eminence above a beast, for all is vanity.' They fill their places so much better than multitudes of men, and seem to answer the Divine purpose in their creation so much better, that it seems very sad to think there is no hereafter for them."

"It is almost as sad to think that some men can never die," Sally replied very soberly. "Still I think we shall have to give up old Rose and all our other dumb pets, when we become like the angels. You remember, Josiah, that passage in one of the 'Essays of a Country Parson,' where the writer represents himself to be seated upon a manger, writing upon the flat place between his horse's eyes, while the docile animal's nose is between his knees. The book is here upon mother's table, I will read it:

'For you, my poor fellow creature, I think with sorrow as I write here upon your head, there remains no such immortality, as remains for me. What a difference between us! You to your sixteen or eighteen years here, and then oblivion! I to my three score and ten, and then eternity! Yes, the difference is immense; and it touches me to think of your life and mine, of your doom and mine. I know a house where at morning and evening prayer, when the household assembles, among the servants there always walks in a shaggy little dog, who listens with the deepest attention, and the most solemn gravity, to all that is said, and then when prayers are over, goes out again with his friends. I can not witness that silent procedure, without being much moved by the sight. Ah! my fellow creature, this is something in which you have no part! Made by the same hand, breathing the same air, and sustained like us by food and drink, you are witnessing an act of ours which relates to interests that do not concern you, and of which you have no idea. And so here we are, you standing at the manger, old boy, and I sitting upon it; the mortal and the immortal close together; your nose on my knee, my paper on your head; yet with something between us, broader than the broad Atlantic.'"

"That is charmingly expressed, my dear," said Josiah, "and it satisfies the reason very well, but still the heart pleads for its accustomed companionship in a better life. It is a point not definitely settled by revelation, and as the belief tends to make men humane in their treatment of animals, I am inclined to think that there may be another life for them."

Sally and Josiah had a good deal of discussion in this vein, all very well in its place, but I could not take any part in it. Sally, I guess, had the best of the argument, but that did not make me feel the loss of old Rose any the less. The tears from under the old spectacles at the other end of the table, were a little too much for me, and I had to keep silence or join the company of mourners outside. Twenty five years, you know, make a great hole in the life of man, and when we are touchingly reminded that they have gone, even though it be by the death of a brute, it is very natural to think of the end. These domestic animals, especially the most intelligent of them all, the horse, have much to do with our moral training. The affection for them, which seems almost as natural and as strong as for our own species, tends to repress cruelty, and the abuse of the power we have over them. The civil law properly recognizes cruelty to brutes as a moral offence. Their kindly treatment is a virtue that makes better citizens, and honors the State.—As old Rose was so near to the family, we honored her with a decent burial. She lies under an old oak in the pasture where she used to graze. Peace to her ashes.

Hookertown, March, 15th, 1862. Yours to command, TIMOTHY BUNKER, Esq.

Abortion, or "Slinking" in Cows Produced by Smut on Corn.

The Belgian Annals of Veterinary Medicine, publishes a statement that the *Ustilago Madis*, or parasitic mushroom which occurs on maize or Indian corn as ergot does on rye, produces abortion in cows fed with it. The article says that in a stable where cows were given maize infested with this parasite, eleven abortions occurred within eight days, when, the cause being suspected and the food changed, no further case happened. The author of the discovery then, to assure himself of the supposed fact, dried and pulverised some of the fungi, and administered six drachms of the powder to two bitch dogs heavy with pup, and abortion was produced in each. This statement should be studied and carefully investigated by stock keepers in the United States, and more attention be bestowed by them upon the feed of breeding animals, as it is very possible that many otherwise unaccountable cases of slunk calves can be attributed to diseased corn. Whether the ripeness of the fungus, or its occurrence on green or dry fodder makes any difference, are points to be settled.

How Much Help Shall we Hire?

It is time to be making arrangements for the next season. The supply of labor, at least in the older States will be, we think, nearly as abundant as usual, notwithstanding the war. If six hundred thousand soldiers have been raised among twenty millions of people, it is only one in thirty three of the population. But at least three-fourths of this number have come from the cities and villages and from other callings than agriculture. A multitude have entered the army who were never very productive laborers, in any calling. They are now earning more for themselves and their families, than they ever were before. In the derangement of business

incident to the war, a much larger number following other pursuits have been thrown out of employment than all who have volunteered from the farming districts. It would not be strange, then, if labor should be even cheaper this season than the last.

We can see no reason either in the supply of labor or in its prospective rewards, why we should not employ as much as usual. If it should be cheaper than usual, it will be a favorable opportunity to enter upon some of those projected improvements which have been waiting the "good time coming," for many years. Almost every farm has swamps and wet land to be drained, pastures to be cleared of rocks, brush, and stumps. The production of such lands may be quadrupled in most cases by a wise use of labor. As a rule, we economize in the wrong place when we refuse to hire help in order to save the wages. Whether we have war or an early peace the Nation must be fed, and all the products of the farm will bring a remunerative price.

Blinks from a Lantern....XXX.

DIGESTS A CHAPTER OF EXPERIENCE.

Just in the valley, in plain sight from Higgin's Rest, lies the snug farm house of William Ruggles. You can see the smoke from his chimney on any of these still winter mornings, floating lazily away over the river, until it is lost in the distance. It is a gambrel roofed house, painted white, and has been the homestead of the family for a hundred and fifty years or more, since the first settlement of the region. At least three proprietors of the same name have died upon the spot, and the fourth, having passed the allotted term of human life, is likely to end his days in peace not many years hence. The family and the premises are a picture of serene old age, such as can be found no where else but in farm life—and that in this land of freedom, thrift, and intelligence. The old folks, both past seventy, have reached the Indian summer of life, and a Sabbath stillness reigns about the premises the year round. The children have long since grown up, and left home. Mrs. Ruggles never believed in servants, never found the need of one, and so persistently boils her own kettle, and cooks her weekly dish of beans and pork, just as she did forty years ago, without knowing that any thing has happened. Any evening that you may drop in upon her after six o'clock, you will find the table all cleared, the dishes washed, and Madam Ruggles seated in her snowy cap and spectacles, knitting soldiers' socks or mittens. She has a large chest full of stockings and drawers, plenty enough to last herself and Mr. Ruggles through life, should they live twenty years longer, which is not at all improbable. Mr. Ruggles is seated over in the corner, in his big arm chair, with pipe and newspaper, and the cat stretched on the rug before the stove, completes the trio of the family. The old gentleman does not believe in dogs—never owned one—but has owned a great many sheep, and sold a great deal of wool.

Out of doors, everything is about as snug and comfortable, as within. The barn stands back from the house, and has a barn cellar looking out cheerily upon the South, where the cows sun themselves in the brief winter days. The sty is hard by, where three pigs are annually fed, and come to the butcher's knife at Christmas, or a little after. Four cows, and a horse, a flock of sheep, and a multitude of hens and turkeys, complete the stock of the establishment.

There are only sixty acres of the farm, and it is managed with reference mainly to the comfortable support of the old folks, and the cat, rather than for profit. They have enough, as they think, to carry them safely through, and what is the use of working hard to leave money for a third generation. Their own sons and daughters are all thriving, have homes of their own, and are able to take care of themselves. It looks to William Ruggles like a "waste of the raw material" as he bluntly expresses it, to be saving money for folks who know how to earn it for themselves. He does not owe a dollar in the world—has his homestead all clear—has a thousand dollars or more in the bank against a rainy day, and the farm, with his labor, and that of a hired man in Summer, produces almost everything the family needs. Mrs. Ruggles manages the poultry and milk with so much skill, that all the store-bills are paid without any other draft upon the resources of the farm. He has a good orchard, and a large garden, which yield abundantly. The table is always bountifully supplied, and nowhere do friends meet a warmer welcome than in this rural home. Though his farming is nothing remarkable, he is one of the best specimens of manhood that I have met with since I lighted my lantern. He reads the papers, especially the agricultural journals, and evidently well digests whatever he reads.

I found him posted on most of the agricultural topics discussed in the papers the past year. He had read the discussion on the profitableness of farming, and said he did not wonder that there was so much talk about it. He said it used to be so fifty years ago, when he was a boy.

"Most of the young men then had an itching to get away from the farm as they have now. It was generally thought that it was a slow hard way of getting a living, and the boys all wanted to get rich in a year or two, and then lay off and enjoy life. My two older brothers were possessed with this notion, and, to the great grief of my father, went to the city as soon as they were able to manage for themselves. They both lie over on the hill yonder," said he, pointing to the old burying ground; "and their history and mine may be worth relating to the farmer boys who are now growing up, and are soon to determine their calling for life. Jonathan, my oldest brother, left home at the age of eighteen, and served as a clerk in the city for a few years, acquired some property, got well skilled in business, earned a good name, and soon after established himself as a cotton broker in Charleston. He made money rapidly, married happily, and after a few years was able to come on north every Summer, with his family, and spend money about as freely as he made it. He was a man of good morals, and correct business habits, and there was no reason in himself why he should not have kept his fortune, and died a rich man. But he did not. In the business of buying and selling on a large scale, as is generally the case with cotton, there will be fluctuations in the market that no man can foresee. At the age of fifty he had lost all his property, and had to begin life anew in the North. By a second marriage he repaired his shattered fortunes, and for a few years lived comfortably as a clerk in the city. But he accumulated nothing, and by the breaking of a bank, his wife lost everything, and for years before his death, he was supported in part by the charity of friends.

"Robert, the brother next older than myself, left the farm at twenty-one, and set out in business as a clerk in the city. After years of clerking, he became a partner in the business concern in which he was trained, and became a successful merchant. He was at one time reputed to be worth three hundred thousand dollars. But in an evil hour he went into land speculation, and lost every thing. He never married, and never removed from the city. For the last twenty years of his life he lived in poverty, barely earning enough to keep soul and body together. He was so poor and so much chagrined at his reverses, that he never came to see us but once after his failure. I paid his doctor's bill, and his funeral expenses. Neither of my brothers left enough to pay for their grave stones. Both of them had better advantages of education, and had every reasonable prospect of succeeding better in life. My four sisters married farmers, educated their families well, saw them all respectably married, and died in their own homes, surrounded by those who loved and cherished them.

"I knew a good many men of my father's age, whose families turned out pretty much in the same way. In this region, nothing has paid so well as farming. Almost every one, with ordinary capacity for business, acquires property, and when old age overtakes him, he has a comfortable home, and no harrassing cares for the future. With my little farm, and stock, I am as independent as a king, and twice as contented. The children and grandchildren all love to come and see us, of whom we have already over forty, and the old homestead will always be a green spot in their memories."

Flax.

This crop occupies the ground but a short time. It follows corn or the small grains in a rotation, and may be followed by turnips the same season. Any soil finely worked, in good heart, free from weeds, not so rich as to produce a rank, uneven growth, and not liable to suffer from drouth, will answer for flax. Two to three bushels of seed are sowed to the acre, according to the quality of the land; never more than two bushels when raised for seed. Sow early in Spring, harrow and roll. When a hand-breadth high, it is well to go through and pull all the tall growing weeds. About the last of July the bottom of the stalks turn yellow and lose their leaves, the seed capsules also become plump and full. If the crop is raised for seed let it stand until fully ripe, but gather before there is danger of shelling; if for the fiber, pull when the ripest seeds have assumed a light brown color. Flax is pulled by the roots, bound in small sheaves, and stooked until dry enough to stack. Or, the seed may be stripped off in the rippling combs at once and the straw stacked. When raised on a small scale, it is usually spread out in gavels as pulled and left to undergo the rotting process. Twelve to sixteen bushels of seed, and a ton and a half of straw, is a common yield. When the cleansed fiber and the oil are alone sold, this otherwise exhausting crop does not exhaust the farm at all.

A Chapter on Castor Beans—Details of Cultivation and Gathering.

The Castor Bean (*Ricinus Communis*), or Jonah's Gourd, is beautiful as an ornamental plant, and for this purpose it may well have a place in every garden. The quick growing, large, tree-like stems, with monster leaves, even in northern climates, confirm what is believed by commentators on the Bible, that the plant which sheltered Jonah, called a gourd, was no other than our castor bean plant. For garden ornament, it is only necessary to plant a few of the beans in hills, or in a drill, thinning out to 18 or 20 inches apart. The stalks grow from 5 to 10 feet high, or more on rich soil. Both stems and leaves are of a dark, purplish color. Within a few weeks past, several subscribers of the *Agriculturist* have personally assured us from their own experience, that wherever the castor bean is planted in a garden, the moles will surely take their departure. It hardly seems credible, but may be so—especially if moles are as easily nauseated as children with the slightest odor of anything like castor oil. In form and appearance, the fruit resembles common small colored beans. The oil pressed from these is the common medicinal castor oil of the druggists, which is sold in large quantities. We have seen thousands of bushels of the beans in bags on steamboats on the Ohio and Mississippi rivers, which were taken in at towns on the banks of those rivers, along Southern Indiana and Illinois, and some we believe from Eastern Missouri and Northern Kentucky. They will grow well any where south of 40°, and probably further north. There is just now a new interest awakened in the cultivation of this crop in the States above mentioned. A subscriber residing in Saline County, Ill., who has grown several crops successfully, furnishes for the *American Agriculturist* the following directions, which are very full:

FIELD CULTURE.—The yield is 12 to 20 bushels per acre. Prepare the ground just as for Indian corn, but without much manure, or the plants will run too much to stalks. As soon as the ground is warm, and the weather settled, say about the first of May, have the surface well prepared with plow and harrow, and mark it off into rows four feet apart. Then cross-mark it at the same distance, but leave between each set of four rows, a space wide enough to drive through a sled, wagon, or cart. The cross rows should run in a direction to admit of the ready entrance to the spaces left for the team. Plant in hills at the crossing of the rows, the same as corn. As soon as the plants are up, draw a little earth around them to keep down grass and weeds, and as a protection against the cut-worm—taking care not to break the tender stems. When well started, thin out to two stalks in a hill. Cultivate the same as corn.

They will commence to ripen the first of August. Place upon a sled, or on wheels, a tight box holding eight or ten bushels. With two men, and a boy to drive the horse, go through the wide rows or spaces, each man taking two rows on either side, and cutting off all the bunches that are beginning to crack. When the box is full, take it to the yard or bean-house. A yard will do in fair weather, as the sun will soon pop out the beans. If in an open yard, smooth off the ground, and set up crotched stakes about four feet high, and twelve feet apart, laying on poles or rails, and spreading the beans over them as soon as cut and hauled in. Boards should be set around to keep the beans from flying off as they fly out. When thus shelled by the sun, rake off the stems, and sweep up and bag the beans like wheat. They should not be allowed to get wet, and it is much better to have a *bean-house* and use fire heat instead of the sun for curing them. This may be, say 16 feet square, and be covered with boards so closely as to retain the warm air. Put in this a furnace, placing it so that the beans can not fall on it, as from their oily character they readily take fire and burn briskly. Place joists about seven feet high, and over these lay slats, two inches wide, half an inch apart; spread on the beans as gathered, and start the fire, and keep it up until they crack out and fall through the slats.

The gathering from the field can be repeated at intervals of a week or less, as the bunches will continue to ripen until frost. I think the castor bean crop improves old land instead of impoverishing it. The stalks left in the field are tender, and can be broken up readily to plow under, by dragging a heavy brush over the field when dry in the Spring.

Sweet Potatoes Easily Grown at the North—Practical Directions.

During the past three years, we have had good home-grown sweet potatoes, produced with little trouble, and cheaper than we could buy them in the New-York markets, to which they are brought in abundance from the Southern and South-middle States, and sold at moderate prices. Last year a garden plot yielded at the rate of 480 bushels per acre, and there was no reason why a full acre, or ten acres, should not have yielded at the same rate. The soil was of but medium quality, neither light nor heavy. It had a moderate quantity of manure worked into the surface. The manure was a month old compost, made of about four parts of muck to one of horse and cow manure from the stable. We attribute our success in latter years to the method of cultivation. The sweet potato, to be sweet and mealy, and to grow vigorously, needs a warm dry soil, with plenty of sun. To secure this in our latitude, on a soil not clayey, but yet not sandy, we plant in high round hills, which let in the warmth of the sun and warm air on all sides, and secure at all times perfect freedom from water. For garden culture we proceed thus: After preparing the ground well, as for other potatoes, sticks 1 foot long are set up about 3 feet apart each way to mark the centers of the hills. With a hoe or shovel the earth is then thrown up around the sticks on all sides, so as to form round hillocks, 8 to 10 inches high. (In field culture a plow run twice in furrows each way, will do the hilling more economically.) When two or three rows of hills are made, the sticks are drawn out, and used for other hills. As soon as all danger of frost is over, and the ground warm, the plants are set—one strong or two weak ones in the center of each hill, in the holes left by removing the sticks, using a little water, if the ground be dry. They can be set almost as fast as hills of common potatoes can be planted. No further care is needed, except to keep the ground free from weeds, as for other hoed crops. The vines grow slowly at first, but after a time they run vigorously, and are at all times ornamental. Our engraving shows the appearance of the vines, with small tubers attached. The plants we have usually bought in the market at trifling cost. They are frequently advertised in the *Agriculturist*. We shall this year raise our own plants thus: The last of March or early in April, the potatoes are put in soil in the hot-bed, or, if need be, in a box of rich earth set in a warm place. They send up a multitude of sprouts with roots attached; these sprouts are broken off from the tubers, for setting out at the proper time.

FURTHER NOTES.—About the first of March, J. C. Thompson, of Staten Island, sent us some sweet potatoes of his own growth, excellently preserved, and as good as any we have ever tasted at any season. From his full description prepared for the *American Agriculturist*, we add a few extracts on points not referred to above. "....Sweet potatoes may be grown in hills or in ridges; the latter require least labor.... Light sandy loam is best, because it is dry and warm, but small tubers may be produced on quite stiff land, and even on sward or old pasture land thus: Turn two furrows nearly together to form the center of a ridge once in three feet, filling in the open space between the upturned furrows with a light, rich compost to form the center of the ridge, and in this set the plants 18 inches apart. It is better not to disturb the ground *under* the ridges, for then the tubers will not grow long downward, since they meet the hard soil, but they increase in diameter and become nearly round, which improves their appearance and quality. The secret of getting round, smooth, chubby sweet potatoes, instead of long, slim things, is to have a hard bottom under them....Fine, or half-rotted manure will do, using it in the whole soil, or in the hills or ridges, in the same quantity and manner as for the Irish potato....The best time for planting is toward evening, using a little water in the holes, if the ground be dry, covering it over with dry earth, to absorb the excess and prevent baking....If in rows in the garden or field, these should run north and south; as the vines extend, lay them lengthwise on the rows, to allow the sun free access to the sides....Last season I planted sweet potatoes in rows 4 feet apart, with rows of carrots between, and from a plot 50 by 100 feet obtained 17 barrels of sweet potatoes, and 48 bushels of fine carrots. Three feet is the proper distance apart for the vines when grown alone, with the plants set 16 to 18 inches apart in the ridge....The *Nansemond* variety is the best for the North....In August and September the largest potatoes may be taken out for use, leaving the smaller ones to continue growing. Run the finger into the ground near the stem, and when a large tuber is found, remove a little of the earth, detach it from the stem, take it out, and place back the earth." [We have practiced this successfully. ED.] "When frost kills the vines, choose the first clear dry day, dig until noon, let the

tubers lay on the ridges to dry, and before dew falls, pack them in barrels, in the field, with plenty of *dry cut* straw, and then store the barrels in a moderately warm, dry place for winter."

Borecole, or Green Curled Kale.

GOOD "GREENS" DURING ALL THE WINTER.

Here is a most valuable plant which is common in Europe, but is as yet little known among our American readers, though an old friend and favorite upon almost every German table. During the past Winter, while frost and snow have cut down almost every other green thing in our vegetable garden, the borecole has bravely held its position, thrusting its beautifully curled green leaves above the snow when not too deep, and always ready to supply a most agreeable dish of tender greens. We appreciate it more than ever before, and commend it to every reader of the *Agriculturist* having a rod of ground.

In the books it is called *Borecole*; in our seed list (No. 196), we use the common name, *Green Curled Kale*; in the German it is called *Grüner Kohl*; and it is also known as *Scotch Kale*, and *German Greens*. It belongs to the *brassica* or cabbage tribe, and grows similarly to the cabbage, but is without the solid head; it yields a thick mass of leaves beautifully curled, which are free from heavy coarse stems; it endures the most intense cold without injury, being improved for table use by the effect of frost. It is left out during winter, and cut as wanted for the table, even when necessary to dig it out of the snow. It is boiled like other greens, the water pressed out, and served with a little salt, butter, and pepper, to suit the taste, and eaten with vinegar when liked. The leaves are also chopped fine and used in soups. It is remarkably tender, and more palatable, more easily digested, and as nutritious as cabbage—but always better after exposure to frost and snow.

The culture is quite as easy as that of cabbage; a poorer soil is preferable, as in rich or highly manured soil the leaves grow too rank to endure freezing perfectly, and the coarser leaves are less delicate eating. There are large and dwarf varieties, the larger being preferable, as the under leaves make good cattle food, while the inner tenderer leaves may be used for the table. The plant is well worth cultivating as green fodder for animals of all kinds. Our poultry devour all the bits of leaves left. Sow the seed at any time from the last of April to the first of June, in a bed the same as cabbage seed, and transplant like late cabbages upon plots where earlier crops have been removed. It requires no further care except to hoe and keep down weeds. In this latitude, and further south, it is best to plant such portions as are desired for use in the latter part of Winter and early Spring, where they will be shaded by buildings or fences; the sun alone, and not cold, injures it. When cut in Winter, leave the stems, and they will sprout again for spring greens; these may be transplanted to occupy less space.

Noon Marks.

Before Connecticut clock factories turned an article of luxury into a common-place piece of kitchen furniture, they frequently made a noon mark of the house or barn. It stood on a due north and south line, so that when the sun ceased to shine on the east side of the house, it was just noon. Could we mark exactly the shadow of a distinct perpendicular edge, we might know pretty nearly when the sun passes the meridian. This is commonly considered noon, but it is not exactly the true noon, except at four periods in the year. One of these periods occurs about the 15th of April, this year, and a noon mark then made, as some one by a quadrant observes when the sun passes the meridian, will indicate the true meridian or north and south line. A better way still is, to make a meridian line with a "compass," allowing for the variation of the needle at the time and place where it is made. If a person has a very accurate watch and can get the exact time for his locality, a noon-mark may be made any day by marking the edge of a shadow as many minutes, before or after 12 o'clock by the watch, as are stated in almost all of the almanacs under the column headed "sun on meridian."

Fig. 1. Fig. 2.

Clearing-Holes in Earthern Pipes.

Large pipes made of earthern-ware or brick clay are beginning to be more highly esteemed, and justly so, for they answer a variety of ends. The hard *glazed* pipes, 3 to 6 or more inches in diameter are cheap and very useful for drains to carry *off* water. The *unglazed* pipes, or those nearly so, are cheap substitutes for iron pipes to convey hot-air in a green-house, as was shown in the articles on "Green-Houses for the People," in the *Agriculturist*, last Autumn. They are

Fig. 3.

placed together, as in fig. 3, the joints being closed with some kind of mortar. After a time these may get partially filled, perhaps clogged, with soot. Our gardener, F. Otto, gives us a sketch of a convenient "trap" or cleaning hole for such a series of pipes. Every fifth or sixth two-foot pipe is provided with an opening as shown in fig. 1. The earthern-ware cover, fig. 2, is made to fit closely on this, to be stopped tightly with the mortar. To clean the pipes, it is only necessary to remove the cover and run in a wire with a bent end, or a wisp of straw on the end, and by moving it backward and forward draw the soot to the opening where it may be taken out. A similar arrangement would be convenient in drain pipes. The openings would be accessible on removing the covering soil, directly over where they are placed, and any obstruction could be taken out, without disturbing the pipes.

Usefulness of Charcoal in Agriculture.

In reply to several inquiries, we say that charcoal is useful. Whether it acts directly and specifically as a manure, to any perceptible degree, may perhaps be questioned. Whether it decomposes at all may well be doubted, but it acts as an excellent absorbent of gasses and liquids, and so contributes indirectly to the fertility of the soil. Even sparingly used, it increases the warmth of land, darkening its color. When prepared in the old-fashioned way,—piling together twenty or thirty cords of hard wood, and covering it with sods, etc.—we get not only good coal, but also in the sweepings, refuse coal, and dirt around an old pit, a good deal of potash, soda, lime, and some phosphorus. Besides the effect of charcoal and ashes, we have also that of "torrified" or baked earth which is often of considerable importance. Every experienced florist will tell us of the fine effect produced by it, when spread in coarse lumps on the surface of his pot soil. Who has not observed how charcoal dust gives the grass of lawns a dark, rich luster? An acquaintance of ours who frequently burns coal for market, collects the refuse dust and ashes from his hearths, and mixing it with common soil, about half and half, spreads the same over his grass and wheat fields at the rate of about five cords to the acre. The effect, he assures us, is quite marked. The superior greenness of his fields so treated, is noticeable to every passer by. Another farmer uses the leavings of his "coal-hearths" for mixing with manure in his stables, and as a deodorizer in drains, privy-vaults, etc. This compost he uses on corn, potatoes, and cabbages, and where it is used, he has no trouble with worms of any kind, and his crops are large and of the first quality. Cases are not uncommon where charcoal dust is thrown into hog-pens, and in other ways incorporated with offensive manure, uniformly deodorizing the manure, to some degree at least.

In an old garden, once under the writer's care, worms and vermin of various sorts infested the ground. It was almost impossible to raise crops of radishes, beets, onions and cabbages. Lime and salt were tried, but with little apparent benefit. At length, we spread a coating of charcoal dust and salt over the entire surface, and worked the mixture in thoroughly. From that day to this, the worms have diminished, and now are few and far between—killed or driven away by the treatment, we know not which. Another year, we mean to use the same composition under our currants and gooseberries, to see if it will not kill out the moths; and around our young fruit trees to drive away the borers. For young evergreens, and all trees, we presume charcoal dust would prove an excellent dressing.

Wheelbarrows for Farm and Garden.

A good wheelbarrow is a very important implement for both farm and garden, saving cartage, carrying small loads where neither cart nor wagon can go, a great convenience in distributing manure, collecting fruits or crops, moving barrels, and the like. The common form, with flat bottom, movable side-boards and a large wheel, is very convenient for carrying whatever is to be distributed by the shovel, or which should stand upright, as potted plants, or for going through narrow gateways or between close rows, for loading some heavy articles as barrels, and for many other purposes. The common "Railroad Barrow" shown in the annexed drawing is preferable on several accounts. It is much cheaper, costing from $1 75 to $3, according to size and quality. The wheel though smaller is more under the load and thus supports more of it. It may be loaded almost equally well from all sides, the sides being low. The loads are easily "dumped." It may be used for carrying semi-liquid or dripping substances, and is easily arranged to carry grass or hay, by laying in sticks pointing outward on all sides.

(PRIZE ARTICLE.)

On the Cultivation of Indian Corn.

BY ABRAM V. TRIMBLE, CHESTER CO., PA.

Corn succeeds in all varieties of soil possessed of requisite fertility—excepting some which for want of draining are wet and cold for too long a time in the Spring. The only limit to its cultivation appears to be climate, as it requires hot sunshine and a sufficient length of time between hard frosts to allow it to grow and ripen; this for the different varieties will take from four to six months, but if cut before frost it will ripen considerably in the shock.

PREPARATION OF GROUND.

Corn is much planted on a fresh break of sod, and made the first crop in a five years rotation. It will, however, succeed for many years on the same ground, if the strength is kept up by a proper application of manure. Sometimes (in Pennsylvania) wheat or rye is sown at the last working of the corn and pastured through the winter by sheep or cows; and sometimes the corn is removed when cut and the ground sown with winter grain. The first preparation of the ground should be *thorough drainage*, where it is needed, for no crop is more affected by water standing in the soil than this. If surface draining must be resorted to, the best plan is to plow the land in ridges and plant on the top. This will also give more nourishment to the corn in very thin soils; but, except in extreme cases, it is not advisable, as it leaves the ground rough or uneven, and interferes with good cultivation.

Some farmers object to putting fresh manure on corn land, because it makes weeds grow; but, with me, this would be a reason for applying it to this in preference to any other crop, for there is no other in which the weeds are so easily kept down, while destroying them keeps the ground loose. I generally put the manure on the sod the fall before; when put on immediately before planting, if it is coarse and not very well rotted, it will have to be plowed in; but, if it is fine enough to admit, it is best applied after plowing, and harrowed in. The quantity of manure used only be limited by the available supply; I never knew corn to suffer from too much manure. At the same time excellent crops may be raised on new land, or on old sod without any manure. I apply the bulk of the manure to the corn crop, but give a light coat to the wheat. Manuring in the hill, either before planting, or after the corn is up, is sometimes practiced; but manuring the whole surface is better, if it can be done. Though the manure next the seed helps to start the corn, it is of very little consequence after the roots begin to spread over the ground, and there will be little difficulty in starting the corn provided the soil is properly prepared.

PLOWING.

This may be done any time that the ground will admit of it, from the middle of Autumn until planting time. For stiff, clayey soils, Fall plowing is best; it also destroys the cut worm and the seeds of a great many weeds. Sometimes it is considered an object to have the sod for early pasture in the Spring, as it furnishes a good bite for milch cows, etc., before it is necessary to plow it, and while the permanent pasture is too young. In this latitude, if sheep are fed on it in mild weather through the Winter, they will give it an excellent coat of manure. In plowing, leave as few dead furrows in the field as possible. If the ground is nearly level and the shape of the field will permit, the best plan is to begin in the middle and throw the furrow inwardly, leaving a furrow all around the outside, [that is, "back-furrow" the whole field.] This, however, will depend on the number of times the field is to be plowed in the rotation; as, the next time, the furrow will have to be thrown towards the fence and the last plowing before seeding down should always be towards the middle. Do not lay the furrow flat, but edge it so as just to cover all the grass. The depth of plowing will depend on the depth of the soil. If your soil is not as deep as you can run the plow, turn up a little of the subsoil each time, thus gradually deepening it. Subsoil plowing will be of advantage, especially where the top soil is thin. Remove all the stones to the depth that you plow. Give the ground a thorough harrowing, going first the way it was plowed, then crossing until the surface is perfectly mellow.

MARKING OUT AND PLANTING.

If you are going to plant in hills, the next thing in order will be marking out. This is generally done with the plow, running to a pole set up at each end, and others along the row as you can see them, if you can not see through, marking double width as you go towards the poles, and returning through the middle space. I have used for several years a simple and very effective implement for this purpose, which can be made by any person who can handle tools, (fig. 1). Make a cheap axletree of such a length that the wheels tracks will be just twice as far apart as you wish to make your rows. Fit on a pair of light wagon wheels, and fasten a tongue firmly to the middle of the axletree. Half way between the middle and the track of each wheel, fit two pieces of scantling, four inches thick (extending to the ground and rising a little above the axle) so as to slide freely up and down, but not

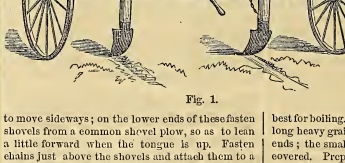


Fig. 1.

to move sideways; on the lower ends of these fasten shovels from a common shovel plow, so as to lean a little forward when the tongue is up. Fasten chains just above the shovels and attach them to a piece fastened across the tongue just behind the evener; shortening or lengthening these chains will make the shovels run shallow or deep as wanted. The uprights should be connected at the top by a piece bolted to them, leaving the bolts very loose in the holes, so that each slide can work independently, and a lever should be arranged to lift the plows out of the ground in turning. This machine will mark two rows at once, and by keeping one wheel in the old track, a good driver can, after a little practice, keep very straight without poles. Rows straight and uniform look better, and add much to the convenience of cultivation. The furrows should be just deep enough not to disturb the sod. The most common distance apart in Pennsylvania is four feet each way. The distance however, depends on the kind of corn, some of the small growing kinds being planted much closer. The following rule will, I believe, apply to all cases. Estimate how many bushels you will attempt to raise to the acre. Put it at one hundred; not that it is often reached, but because it may be reached. There are well authenticated instances of much greater crops, but this will do *to begin with*. Find the weight of corn on a good, full sized ear of the variety you intend to plant; and dividing the weight of 100 bushels by it you will know the number of ears you want to raise on an acre, supposing them all equal to your standard. If the corn is of a kind that generally bears one ear to the stalk, the number of stalks will, of course, be the same. Do not calculate to raise more than one good ear to a stalk, and having the number of stalks in an acre, divide this by the number in a hill (say three). This will give you the number of hills to the acre. The number of square feet in an acre is 43,560, which divided by the number of hills gives the number of square feet required by each hill, and the square root of this number is the distance the hills should be apart. In no case, however, should the rows be less than three and a half feet apart for convenience in working. If this will not make it thick enough it will be better to plant in *drills*, making it close enough in the rows to give the required number of stalks. The advantage of a plan like this is, that it is founded on, first raising good ears, and then as many of them as possible. Drilling is a very good way of putting in corn if you are certain of having help enough at the right time for thinning and keeping clean. As it can only be worked one way by horse, more has to be done by hand labor.

PLANTING

may commence as soon as the ground is warm and all danger of hard frost is over. In this latitude (40° N.), this will be from the first to the middle of May; but I have seen very good crops that were planted as late as the first of June. The greatest danger in late planting is the liability of injury by frosts in the Fall. In selecting seed, more attention should be paid to the appearance than the name. There is scarcely any end to the varieties raised, and the same kinds have different names in different sections of the country. You will have to be governed in your selection very much by climate—some kinds requiring a much longer season than others. At the North, Dutton, little Canada, King Philip, and many of the eight and twelve rowed yellow and white flint varieties are favorites. The large gourd seed, a strong growing and not very heavy variety, is much raised in the middle States, and requires a long season. Southern white is much raised at the South, and some persons here prefer it for cooking. Stowell's evergreen is one of the best for boiling. For seed choose good sized ears with long heavy grain and small cob, well filled over the ends; the small end of the cob should be entirely covered. Preparing the seed with gas or common tar will prevent birds taking it. To do this, soak the seed about twelve hours in cold water, then pour off the cold, and pour on warm water just below the boiling point, enough to barely cover the corn. Dip a paddle in the tar or pour a little on the corn and stir till it is all coated with the tar. A very little of the tar will go a great way. When you have it completely coated, drain the water off and sprinkle on plaster, stirring it up with the corn until it becomes thoroughly dried and the grains separated. If you are not sure of all your corn growing, drop enough in each hill to be certain of having enough, and thin down to the right number of stalks after it gets well started. If the seed was properly saved, there will be very few grains that will not grow. Thinning corn, though apparently a very simple operation, is very hard to do well. Some of the stalks will break off in the ground, leaving the roots to grow again; and I have found very few men or boys who would always leave just the right number. When birds and other depredators commence on a hill, they generally take it all. My experience is, that three stalks to a hill will bring more corn than any other number, and I make the hills three feet ten inches apart each way. Cover the seed with a hoe about two inches deep, taking care not to put on lumps or stones.

PUMPKINS AMONG THE CORN.

It is a common practice to plant pumpkins among corn, and about it there is a variety of opinion. Some assert that they take no nourishment from the corn, and others, that they deprive it of more than their value. The truth probably lies between the two extremes. They most likely take some nourishment that would otherwise go to the corn, and a great deal that would not. If your only object is to raise a large crop of corn, leave pumpkins out. If you want to get the greatest possible return from

your land, plant them. Two seeds in every other hill and only in every other row will be enough.

AFTER CULTURE.

As soon as the corn is fairly up, so as to show plainly in the rows, I commence going through it with the "cultivator," twice in each row, as near to the corn as possible without disturbing it, replanting any that is missed. If planted in rows both ways, I work it first one way, then across. I aim to keep down all weeds and grass all the time that the corn is growing, hoeing where it can not be reached with the cultivator and pulling the weeds by hand where necessary. When the corn gets about a foot high, or as soon as I can get through without covering it, I go over it once each way with a double shovel plow, twice in a row. Afterwards, use the cultivator as long as I can get through it without breaking the stalks, using a short whiffletree when it gets high. After it gets too high to take a horse through, I keep down all the weeds that appear with the hoe or by hand.

ENEMIES.

Blackbirds, crows and other birds are sometimes troublesome in taking up the seed, both before and after it comes up. This can be prevented to a great degree by preparing with gas tar, as directed. They also sometimes take a considerable quantity from the ears while it is standing; but, on the whole, they do the crop a great deal more good than harm by the immense quantity of worms which they destroy. Rats and mice destroy the corn in the shock and after it is stored if they can get at it. Mice also sometimes take the seed in the ground but not often, unless, as some say, they follow in the tracks of the moles. It is the opinion of some people that moles do not eat corn, but be that as it may, I have always found it missing when it came in their way. Cultivation interferes considerably with their operations by breaking up their underground passages. When you replant, leave their tracks undisturbed and plant a little on one side. They will seldom go out of their way. (In replanting generally, do not break the ground any more than you can help.) Ants sometimes do the young corn great injury by making their hills around the stalks, especially after it has been cut off by worms. A dose of ashes will drive most of them away. Scratching around the stalks also clears them out. The cut worm is a brown worm about three-fourths of an inch long when fully grown, but commencing its ravages when it can scarcely be seen. It cuts off the young shoots at the surface of the ground. It is most active in cool and cloudy weather, the hot sun driving it into the ground. The corn generally grows out again and often does not appear to sustain any permanent injury. Plowing in the Fall is a partial preventive, probably destroying the pupæ or the eggs by exposing them to the cold. The most effectual remedy would be to let alone those birds which eat the worms. "Heart worm" as it is called, affects corn in all varieties of soil. It is not settled whether this is caused by an insect or by some peculiar property of the soil. It is not a want of general fertility, for the same places bring good crops of other grain and of grass. Neither is it altogether attributed to wet ground, for I have sometimes seen it in very dry places. It is, however, most common in stiff, cold clays. The corn thus affected appears suddenly to stop growing, sometimes after making a very fine start. After a time, generally as it begins to ear, it falls partly down, the stalks falling away from each other. The ears on such stalks are seldom well filled and do not ripen well. The roots have a blackened and blasted appearance, and some of the main ones are entirely destroyed. I have sometimes found a small red worm among the roots so effected; but whether that is the cause of the mischief or not, I am unable to say. The ground where corn is thus affected should be thoroughly drained, if at all wet, and the corn kept growing strongly by a liberal application of manure.

HARVESTING.

If the corn is to be shocked on the ground, make the "horses" (four hills tied together for supports,) as soon as the blossom is fairly off. A convenient size to make the shocks is six rows each way, making thirty six hills to the shock. The horse should be made of four hills, leaving four rows each way between the "horses." Take two of the hills that are diagonally opposite and bend them together, crossing the tops. Lap the tops of one of the remaining hills once around the tops thus crossed, and gathering all together in an upright position, lap the tops of the remaining hill around all and tuck in the ends to hold them fast. If the corn is drilled you will have to make the shocks in rows one way and estimate the distances the other. By making the horses early you have them secure in case the rest of the corn is blown down. Commence cutting as soon as the husk on the ears begins to die, or sooner if hard frosts are apprehended. If cut green, care should be taken to let all the buts touch the ground and to spread it evenly around the shock so as not to have too much in one place. The most common implement for cutting is a knife made of a piece of an old scythe about two feet long. Take hold of the tops with the left hand, or gather them in the arm and cut the hill with a stroke slanting from the ground upwards. Cut low enough to keep the ears off the ground, set up carefully, with an equal quantity on each side of the horse. The accompanying diagram will show how to cut a shock to the best advantage. Begin with the hill marked 1, and cut in succession, 1, 2, 3, 4. Thus you will finish each armful at the shock and save much carrying. You also secure an equal quantity on each side of the horse, making two armfuls or eight hills to the shock. This may seem too simple to mention, but most men slash away till they get as much as they can carry, often finishing as far as they can get from the shock, and piling the stalks without system on whichever side comes handiest. The shocks should be bound by a band of rye straw or by a couple of stalks, *first broken between the joints;* after passing them around as low down as you can make them reach, draw tightly together, wrap the tops

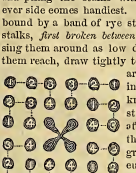

Fig. 2.

around the buts and tuck in. The stubs should be knocked off with a sharp strong hoe immediately after cutting the corn, as they cut much easier while green. The practice of cutting off the tops and blades, leaving the stalks with the ears on standing till husking time, is not so customary here as it used to be, but is much more common at the South.

HUSKING may commence as soon as the corn is ripe enough to keep, which, here, is generally about the middle of October. In husking a shock, we first cut off the horses, then pull the shock over, so as to make four shocks fall towards each other, throwing the corn into a heap between. The more care taken to spread out the shock evenly, the less time will be required to husk it, and the fewer ears will be left in the fodder. The best husking pegs are of iron with two holes to pass a strap through, which goes around the two middle fingers; the end a little bent to fit to the forefinger, and the point flattened and a little hooked. Leave the husk on the stalk and when the shock is husked tie up the fodder in bundles with bands of rye straw. In gathering up the bundles do not push the fodder together, but rather *roll* it; this makes a solid sheaf. We put the fodder from sixteen shocks of corn into one stook. A good husker will husk and tie up the fodder of from thirty to fifty shocks in a day. Select the most perfect and best ripened ears for seed. These should be kept in a place where there is no danger of freezing; a very good place is on a rack hung up in the kitchen or some other warm room; or the husks may be left on to hang them up by. I have had corn kept in this way, every grain of which grew, while that kept in a cold place did not half come up. Pick out all the sound ears and put them in the cribs, keeping the nubbins or soft corn separate to be fed out first. If the weather be warm or the corn not very dry, do not pile much of it together. We use cribs not more than five feet wide, and twelve feet high, the sides of strips just close enough together to prevent the ears from falling through, and the roofs so made as to be raised up on one side to allow the cribs to be packed full. There should be a door in the side or end of each for taking the corn out. To keep out rats and mice, set the cribs two feet above the ground, on posts firmly planted and topped with tin.

The fodder may be kept, either in the barn or in stacks. If put in a mow it should be very dry when taken in, or it will mold. Make the stacks of a little less in width than the length of two sheafs, about 12 feet high and as long as you please, laying the tops together and keeping the middle full by an occasional extra course on top. Towards the top draw the sides in nearly to a peak; and top off by setting sheafs upright on each side and bending the tops together.

The corn is shelled by machines run either by hand or horse power. It should not be shelled until wanted to sell or for use, as it keeps much better in the ear. If going to market, it is run through a fan mill after shelling to clean it from dust, pieces of cob, etc. It is sometimes sold in the ear, and then a double bushel is given, or seventy lbs.—fifty six being the standard weight for a bushel of shelled corn. The proportion between the corn and cob varies much, however, in different varieties and stages of dryness and ripeness. The best time for selling is whenever it will bring a fair price. The *best* way of disposing of it is to feed it on the farm. Some of our best farmers will never allow an ear to go off their land, except in the shape of beef, mutton, pork, poultry, butter, etc.—justly considering that they gain more in the manure than they loose in the price of the corn.

Boussingault says, "This is the true wheat of the Americans," and indeed it seems peculiarly adapted to our wants. Growing in all kinds of soil, and a wide range of climate, and furnishing food for man, and all kinds of domestic animals, it is almost impossible for an American farmer to imagine how any people have ever done without it. It is certainly the most economical grain crop that can be raised. The yield is greatest both for the ground and the seed—sometimes producing a *thousand fold*, thus requiring but a very small proportion of the crop to be kept for seed. The stalks are of more value for fodder than the straw of any other grain and the cobs are worth a good deal for fuel.

Cotton Cultivation.

The impression that the culture of cotton is not understood at the North, should deter no one from at least experimenting with it. It may be raised precisely like corn, in drills, or with a single stalk in a hill, for it branches in all directions. Plant the upland, or furzy seed, on rich soil, as soon as danger of frost is over. The rows may be 4 feet apart, with seed 9 to 10 inches distant, removing half the plants if all vegetate. If seed is plenty, plant still closer to secure a good stand. Cover with fine soil one inch deep, and then treat the field as though it were corn, using the horse and hand-hoe to keep down weeds. As soon as the first bolls open, pick the cotton; and repeat the operation at intervals as successive bolls ripen. Early frosts will very likely cut off a portion of the crop, but if the season is at all favorable, enough will mature, south of 40°, to pay for the trial. Besides, there is no doubt that persistent efforts, using the earliest matured seed of that grown at the North, will so acclimatize the plant that it may be grown in much higher latitudes than at present. The prospect now is, that the amount of cotton planted at the South this year, will be far below the usual quantity, so that northern grown cotton will probably find a ready market. New or pretty rich soil, is best for the cotton plant. It is considered somewhat exhausting to the soil—unless kept up by manuring. See our large prizes for specimens to be exhibited at the *Agriculturist* office next Autumn, (February number, page 64.

WANT OF CONFIDENCE—FROM A PAINTING IN THE ROYAL ACADEMY, BY GEO. THOMAS, (LATE OF NEW-YORK.)

(Engraved for the American Agriculturist.)

No animal awakens stronger affections in man than a good horse: when well treated, a faithful friend, a willing servant, a patient drudge—discriminating, forgiving, self-sacrificing, courageous, ambitious and proud: when abused, obstinate, willful, and treacherous, to the last degree. He shows his character in his eye, and while a child will shrink from one with fear, it will approach another with confidence. Even the great rough head in such close proximity to the tender child, (as seen in the picture above), causes no fear, and we can see the growing confidence which will soon proffer the fragrant clover heads. Tim Bunker gives an affecting history of his family mare, on another page; and this beautiful picture will pass well for a portrait of "Old Rose" and 'Squire Bunkers' grand children. A horse trained by kindness to find his highest pleasure in the society and doing the will of man is not "broken" at all, but made a firm friend. To "break" a colt indicates to most minds a beating, bruising, pounding, whipping operation, out of which the colt comes, saddled, bridled, and broken to halter, bridle, saddle and harness; and doubtless many a colt is thus treated, and broken in spirit and spoiled in temper. May we not lay this abuse to this use of the word *break*. The only idea that should be conveyed and the only practice suffered, should be that of a firm, gentle control, winning the confidence and inspiring willing, affectionate obedience, on the part of the horse. Thus may be developed all those desirable qualities which his fine nature possesses, and we be put in possession of an honest, faithful companion, and helper for the term of his natural life.

Six Best Shade Trees (Deciduous).

The inquiry is often made of us—which are the best half-dozen shade trees? It is said that one man praises this tree, another that, and another that; which do long experience and observation prove to be the best? An important question, which the writer will try to answer.

1. *The White Elm* (*Ulmus Americana*).—Some persons would, perhaps, give this post of honor to the Sugar Maple; but we think that, all things considered, it belongs to the Elm. Nor do we forget the merits of other species of this tree. The Dutch cork bark elm is very hardy, luxuriant in foliage, and rapid in growth, but it lacks the loftiness and graceful dignity of our native tree. The English elm, in its several varieties, is very fine, and so is the Scotch; whoever has room for an assortment, should include these. But the noble native tree must bear away the palm. It grows in nearly every part of the country, is easily transplanted, and grows rapidly.

2. *The Sugar Maple* (*Acer Saccharinum*).—Not lower than the second place, surely, must we put this tree. It is a sober, matter-of-fact tree, with some of the graceful poetry of the elm; its branches do not droop and sway, and float about with the caressing wind. It has a round, bushy head, makes a dense shade, and has a breadth and massiveness of foliage which is really refreshing to behold. Some persons insist that the *Scarlet flowering* (*Acer rubrum,*) is most ornamental. Every tree-lover delights to see its gay red tufts opening in early Spring, before a single leaf appears on any tree, and when the only signs of reviving vegetation are the adventurous catkins on the willows and poplars. Then, too, it grows rapidly, and grows everywhere. And it has a certain freedom and play of the leaves, which we do not find in the other species. Others stand up for the *White leaved Maple* (*Acer dasycarpum,*) which differs from the scarlet chiefly in having pale flowers, and a silvery under-surface to the leaves. The *Black Maple* (*Acer nigrum*), is a favorite with some persons. It differs from the rock maple chiefly in its larger and more leathery leaves; the bark is also darker. Nor must we fail to commend the *Norway* species, which has singularly fine foliage, hanging in dark, rich masses. But for general planting, the old Sugar Maple stands at the head. Its leaves open early in the Spring, they are of a dark, healthy green in mid-summer, and in the Autumn take on all the rich shades of gold, scarlet and crimson.

> "Tints that the maple woods disclose,
> Like opening buds or fading rose,
> Or various as those hues that dye
> The clouds that deck a sunset sky."

If any one wants to try his hand at grouping trees, and to be sure of making no blunders, let him set the scarlet and sugar maples and the white ash together, alternately, and the effect will be very fine. And to give his picture a little deeper tone, work in a few evergreens.

3. *The Oak* (*Quercus*).—This monarch of the forest is less commonly planted than some other trees, because of the difficulty of moving it when large. Cut off the tap-root, and root prune once or twice while the tree is comparatively small, and it can be easily handled afterwards. No one will dispute the high claims of this tree. Its wood is valuable for many purposes. It is a most hardy tree, and lives to a good old age. It has a certain grandeur and sturdy majesty, really elevating. The poetic and historical associations connected with it are such as no other tree can boast. It must stand very high on our list. Of the forty different species of oak in America, the most common, if not the best, is the *White Oak* (*Quercus alba*). In deep soil, it often attains to seventy or eighty feet high, and the branches stretch wide on every hand. It may be distinguished in Winter from other species by rough, whitish bark, and by the dry leaves which adhere to it through all the cold season. —The *Scarlet Oak* (*Q. coccinia*)—so-called from the tint of its leaves in the Fall. The foliage takes on its purplish crimson hue quite late, and is singularly rich. It is a noble tree, grows as lofty as the White Oak, and is a fine tree for grouping.—The *English Royal Oak*, (*Q. robur,*) is a grand old tree, lofty, and spreading its huge arms over the ground magnificently.—Beside these, we have the Rock Chestnut Oak, the Chestnut White Oak, the Yellow, the Pin Oak, the Over-cup White Oak, etc., all of them hardy and desirable in a collection.

4. *The Linden* (*Tilia Americana*)—more commonly known as the *basswood*, is desirable for its rapid growth, its large healthy looking leaves, and its round, symmetrical form. The wood is rather tender, and the tree liable to bruises. The foreign species is popular at home as a park tree.

5. *The Ash* (*Fraxinus Americana*).—The White Ash makes a handsome tree, in its general outlines, in the smoothness of its limbs, the unchanging green of its foliage in Summer, and its beautiful purplish tints in the Fall. The *Mountain Ash* (*Pyrus Americana*), is one of the best trees planted (if we allow ourselves to include under the Ashes a tree properly an Apple). The European variety (*Pyrus aucuparia*) is finer than the American. They are both particularly suited to small grounds, being trees of medium size.

6. The *Cucumber Magnolia* (*Magnolia acuminata*). One of the noble aristocratic family of magnolias, gaining its common name from the appearance of the young fruit which somewhat resembles a green cucumber. It is the most robust member of the family, being found *wild* as far north as Niagara County, New-York. It often rises to eighty or ninety feet in hight. The bark of trunk and limbs is symmetrical and handsome. The leaf buds in Winter are covered with a white, velvety down, which is conspicuous. The leaves are often six inches long and four broad, and of a bluish green color, white underneath. Its flowers are six inches in diameter, of a yellowish white, and slightly fragrant. This tree should be transplanted when small, as its roots are succuleut and brittle, and do not easily recover from injuries. We put this tree last in our list, but not because it is least deserving. For amateurs, it will almost rank number one.

The above is our list of six excellent shade trees. We have not forgotten the merits of such trees as the Walnut, Chestnut, Beech, Tulip, Buttonwood, Birch, Willow, and Horse-chestnut; but these have greater defects than those we have first named. May many of them be planted throughout the country, this very Spring.

Ribbon Gardening.

This is a method of arranging plants so as to represent ribbons or scrolls. It is easily performed by any one, and is a pleasing addition to even the humblest yard. A curved or wavy bed is cut out in the smooth turf of the lawn, say four feet wide and ten or fifteen feet long. Certain suitable colors for the ribbon having been fixed upon, (perhaps red, white and blue,) plants are to be selected which will give these colors. No one set of plants is better for this purpose than verbenas. A row of scarlets or crimsons is set on one side of the bed and along its whole length; next, a row of whites and then a row of blues. These as they grow are to be pegged down and confined to fixed limits so as to represent stripes of color. Geraniums may be used for the same purpose, though they make a coarser ribbon, and give only the different shades of red, pink, and white. I used, it will be quite effective to set either a golden or silver-edged variety on one edge of the ribbon. Petunias, Ageratums, Pyrethrums, Cupheas, etc., answer very well in making ribbons. Annuals may be used for the same purpose, but they do not come into bloom until late in the season. German Asters, for instance, their different colors arranged in rows, make a grand display. Portulacca, Candytuft, Phlox Drummondii, Eschscholtzia, Clarkia, and others of like habit, are quite desirable. These ribbons, to be most effective, should be *looked down upon* from above, say from a window, or balcony, or high porch. The grass around them should be kept shorn quite short and smooth, and the colors kept rigidly confined within their limits.

[PRIZE ARTICLE.*]

On the Cultivation of Flowers.

BY A. J. C., NORWICH, CONN.

The Location.—Fortunately for that large class of cultivators who, in selecting a plot, have only "Hobson's choice" (this or none), there are flowers enough which are not so dainty but they may be successfully cultivated in a soil that affords sustenance for any sort of vegetable growth. Certain kinds may be found to flourish under almost every conceivable variety of circumstances. Let those however who have any considerable space from which to select a spot to devote to their floral pets, bear in mind that the action of the rays of the sun, the great delineator of all the gorgeous shades and delicate pencillings which give to flowers their almost unearthly beauty, is of the first importance to every garden. For those kinds which require a partial shade, such as Pansies, Fuchsias, etc., a sheltering wall or building, or even tree, (the former two preferable) can generally be found; if not, any person with a tolerable share of ingenuity can devise a screen of some sort for this modest sister-hood.

The Soil.—The different varieties of flowers require as many different varieties of soil to bring them to perfection, it would be hard to find a locality where many kinds would not flourish, at least moderately. Lightness of soil is always more or less a desideratum, and the various degrees of richness are easily attained by adding more or less fertilizing material, according to the wants of the plants to be grown in any particular spot. Flowers will not flourish without suitable nourishment any more than a crop of wheat or potatoes. If you have a stiff clay soil, dig in a good proportion of sharp sand, and do not imagine that lightness is necessarily incompatible with richness.

Manures and Tillage.—The best fertilizers, for land not too much exhausted, are common barn-yard manure, and leaf-mold, both well rotted, and which, to have the best effect, should be applied in the Fall. Cause the soil to be thoroughly dug and pulverized, and spread with manure. A slight sprinkling of sulphate of lime (plaster) prevents the evaporation of gasses, and holds them for the benefit of the future vegetation. It is not absolutely essential that this be done in the Fall rather than in Spring, but there are several important advantages gained. By being loosened and thrown up, the soil is laid open to the action of the frost, which renders it light and friable. If the ground be left in ridges, a few sharp freezings will destroy much of the latent insect life which it contains, and which, if left unmolested, will not fail to prey upon your choicest plants the ensuing Summer. The Winter snows, too, bring down with them a large proportion of ammonia, which affords nitrogenous food for plants, and

*The Committee worked long to decide between the above and three other excellent articles. This seemed most practical. They will probably all be soon published in some form.

which, of course, is more fully absorbed by ground prepared for it, than by that left hard and stiff. The elements of manure act upon the soil only in a state of solution; hence, the Winter rains and snows are invaluable in taking up the soluble, which are the valuable parts of manure, and washing them down into the soil. To derive full benefit from this, the ground must be, as before stated, light and porous, that it may act as a filter, retaining those elements important to vegetation. Ashes will be found a powerful auxiliary to the cultivator of flowers. The ashes of wood or leaves, contain a large portion of those elements useful to the life of plants, which they draw from the soil; and therefore, if we supply them to the soil a fuller and more luxuriant growth must be the consequence. Ashes also act mechanically, particularly upon sticky clay soils, by interposition: the cohesion is destroyed, and by that means water and air, Nature's most powerful agents, are admitted. The small fragments of charcoal contained in ashes are in no light degree conducive to the growth of plants.

Concentrated Manures.—The use of guano and other concentrated manures, I would advise to defer until the growing season, at which time they should be applied diluted with a large admixture of some other substance, or in water. Guano has a burning tendency, which, in a dry season, is sensibly felt by delicate flowers. On cold, wet land, and in experienced hands, it is undoubtedly of great utility, but I would recommend the novice to be chary in the use of it. Roses, and a few other plants that bear stimulating, thrive well under its application, provided other manures be available to the plant at the same time. A mixture of three parts pulverized charcoal or leaf mold, and one part guano, may generally be used with safety; but a better way of using guano is to apply a solution of it (1 lb. guano to 10 gallons of water) to growing plants a moderate watering once in a week or ten days. If the season be dry, do not use it so freely as in a wet one. For pot-culture, and particularly for forcing, guano is to be recommended, as the soil in pots is generally changed as often as once a year; and it is also easy to keep it moist. One ounce sulphate of ammonia dissolved in two gallons of water, and applied occasionally, will promote a healthy and vigorous growth of green stalks and leaves, but does not, I think, increase the number of flowers.

Plan and Arrangement.—It would be vain to give any directions for laying out a flower-garden, for in no one thing is greater diversity of good taste displayed, than in this very matter of flowers and their arrangement. If the preparation recommended, be made in the Fall, your plot will be ready for successful planting in the Spring. This bed, is the time for laying it out, in squares or parallelograms—circles or triangles—palm-leaf patterns or geometrical non-descripts—as your fancy dictates. I would only say to the novice, be your space great or small, do not cut it up too much. If you have little room, you have none to spare for unnecessary walks, and alleys; if your plot be large, you gain a much more beautiful effect from a continuous regular or irregular bed, than from the same space cut up into little patches. To place the taller growing plants in the back ground or center (oftener the former) is generally considered desirable; but the arrangement must of course be in a great measure determined by individual taste, the location of the flower-garden, and the points from which it is viewed.

FLOWERS GROWN FROM BULBS.

Hardy Bulbs.—The first Spring flowers that greet us, in these Northern latitudes, are the Snow-drop and Crocus, which come peering their pretty heads to us through the snow, or almost breaking their slender necks in desperate effort to force a way through the frozen ground. Next come Jonquils, the different kinds of Narcissus, and Hyacinths and Tulips, in their many varieties, making glad the month of May, and closely followed by the Crown Imperial and Iris. Then comes the stately train of Lilies, forming one of the chief ornaments of the garden until the first of September. All these should be planted in the Fall, in a rich compost, composed of one part well rotted cow-manure, one part sharp sand, one part leaf-mold, and one of good garden loam. Any bulb will thrive in this compost. Though not essential, a covering of leaves, two or three inches in depth, is highly advantageous, during the winter months, to all out-door bulbs, particularly those newly planted. A slight sprinkling of loose gravel, or a few old boards, will serve to keep the leaves from blowing away. *Crocuses* and *Snow-drops*, from their low growth, are particularly adapted for borders; or planted thickly upon a bank or slope, in full view from some favorite window, they have a charming effect, are perfectly hardy, and will flourish even in very exposed situations. The most satisfactory, though the most expensive way of procuring all flowering bulbs, is to order *named* varieties direct from the importers. You are more sure of getting good bulbs in this way, than in any other. Some of the best varieties of Crocus in cultivation are the Caroline, pure white; David Rizzio, purple; Cloth of Gold, yellow; Dickens, bright blue; and Prince Albert, deep rich maroon. The double sweet *Jonquils* are, I think, more desirable than the single ones. They are easily cultivated, and in favorable localities send up their fragrant canary colored blossoms as early as the middle of April. The Garden, and Polyanthus *Narcissus* afford early and fragrant flowers for bouquets and vases. No flower-garden should be without at least one or two sorts, for they proffer their bloom at a season when flowers are rare and difficult to obtain, and should be prized accordingly. Of the Polyanthus Narcissus the best varieties are, perhaps, the Double Roman, white and orange; Grand Primo, and Paper White, both clear white; and States General, lemon color deepening to orange in the center. Of the common Garden Narcissus, very superior varieties are the Double White, and the *Narcissus poeticus*, which latter is single and pure white, marked with red, commonly known as the Pheasant Eye. All the other varieties, of which I have any knowledge, are yellow, with not very strongly marked differences. The varieties here mentioned, with perhaps one or two yellow ones selected according to the fancy of the owner, will be enough for the amateur to commence with in any case for beginning. *The Hyacinth* comes next, which, with its numberless and peerless varieties, demands a chapter by itself. Probably the cultivation of no other bulb, if we except the Tulip, has been carried to such perfection as that of the Hyacinth. If you are willing to take a little extra pains in planting these bulbs, they will amply repay you by their luxuriant and gorgeous bloom. The following method, which I found a year or two ago in the Country Gentleman has been attended with unexpected success. "Mark out the space you intend to devote to Hyacinths, and excavate it to the depth of fifteen or sixteen inches; then throw in about two inches of small stones for drainage, and spread over them a thin layer of well-rotted cow-manure; fill up the bed with compost, raising it four or five inches above the surrounding level, to allow for settling. Hyacinths planted in a bed prepared in this manner, set six or eight inches apart and four inches deep, and protected with leaves or straw, can not fail to do well. The immense number of these valuable bulbs now in cultivation, renders it impossible to select a few which would claim pre-eminence over all the rest. The limits of the present article forbid the mention of more than a very few favorites: The Couronne Blanche, white; Herman Lange, rose-tinted; Bride of Lammermoor, dark blue; Globe Terrestre, light blue and white; La Garland, crimson; and Princess Esterhazy, yellow; these are all very beautiful, but not more so than a hundred others I might name.

Tulips.—Much of the gay bloom of the garden, early in the season, is dependent upon Tulips. The great rage for these flowers, which prevailed so extensively a few years ago, has very much abated—a fact which, fortunately, can not detract from the innate beauty and richness of the blossoms which the bulbs continue to send forth every Spring, notwithstanding the comparative obscurity to which they are consigned. Tulips require to be planted with great regularity; if this precaution be neglected, the beds will present a ragged, slovenly appearance, far from pleasing. Plant them, therefore, in straight lines, about six inches apart and with the taller kinds in the center. Of course the hight depends somewhat upon the strength of individual bulbs, as well as upon the particular variety which they represent. Double Tulips are not so desirable as the single: they are coarse, with thick, muddy coloring. The striped Mariage de ma Fille forms a bright exception to this rule. Among the best single varieties, are the Silver Sceptre, pure white; Monument, white ground, marked with cherry; Abbesse de St. Denis, lemon with delicate crimson lines; Beauté Supreme, purple; and La Matelas, deep rose. The Florist Tulips are taller and of later bloom than the foregoing, and are highly valued. Rose Bybloemens and Violet B., white grounds flaked with rose, purple or crimson, combine most of the attractions to be found in this class. The collection will not be complete without a few of the picturesque Parrot Tulips, with their curious intermixtures of green, yellow and crimson. The Markgraf, yellow and green, and the Perfecta, scarlet, yellow and green, are preferable to any others within my ken.

The Crown Imperial (Frittelaria Imperialis) is a fine showy plant, sending up shoots two or three feet high, which bear wreath like clusters, of showy lily-like flowers, which emit an unpleasant odor, and are therefore not desirable except in a large collection. It is suited to any good light garden soil.

Iris.—The different varieties of bulbous Iris (Flower de Luce) form a very attractive class of plants. Most of them are of different shades of blue, though some are pure white, and others bright yellow. *Iris Persica* is a desirable blue variety, being fragrant and early. *Iris pavonia*, white spotted with blue, is also to be recommended. After the time of blooming is past, the bulbs should be taken up and dried, and replanted in the Fall, as they are apt to rot if left in the ground.

Lilies.—Next in order come the lilies—the fairest and proudest ornaments of the garden. The double white garden lily is earlier than any other, blooming in May or early in June. Next comes *Lilium bulbiferum*, enlivening the month of June with its bright orange tints, and closely followed by the white lily, *L. candidum*, cultivated in every garden, and decidedly common, yet always presenting, in its fair stately beauty, a claim to a place in even the most limited collections. *L. Longiflorum*, also bears snow-white flowers, very fragrant and delicate, on stems about a foot in hight, a week or two later. The superb Japan Lilies, which have only recently been cultivated to any extent in this country, but which are fast becoming indispensable to every amateur, display their bloom in August and September. Some of the new seedlings are as yet quite expensive, but the varieties first introduced—*L. lancifolium album*, pure white; *L. lancifolium rubrum*, white, spotted with crimson; and *L. lancifolium punctatum*, white, spotted with pink—are within the reach of all, and have beauty enough to satisfy ordinary mortals. Those desiring the newer and more expensive bulbs, will find—in the "Meipemone," dark crimson; "Ursulia," deep pink with dots of a yet darker shade; and "Terpsichore," dotted white—ample return for the additional outlay.

All the above (except Tulips) thrive vigorously in the compost recommended for Hyacinths. The subject of bulbs is far from exhausted, but the limits of the present article make it necessary to pass by some varieties well worthy of cultivation. By a judicious arrangement of those already mentioned, however, and by planting in connection with them tender bulbs, set in the Spring, it is easy to secure a succession of bloom from April to October; and a bed of flowers gives more abundant reward for painstaking cultivation. All bulbous plants should be watered with liquid cow-manure while in bud.

FLOWERING SHRUBS, ETC.

No collection, however small, can afford to be with out at least one or two of the many easily grown flowering shrubs with which Europe and Asia are the larger kinds are hardly suitable for the flower-garden proper, but there are many whose dimensions make them quite admissable. There is the *Spirea* family, of which the most beautiful is indisputably the peerless *Spirea Reevesii flore pleno*, brought several years ago from Japan, by Mr. Reeves. It is quite hardy, only in rare instances showing any bad effect from the most intense cold of this latitude, (4° 30′); and in June, when the slender branches are covered with thick clusters of tiny flowers of the purest white, it forms one of the principal attractions of the garden. In choice and elegant beauty nothing can excel it. The Chinese Flowering Plum (*Prunus Sinensis alba flore pleno*) of yet later introduction, has, I believe, been fully tested in its ability to endure our winters. It bears a profusion of pure white flowers in June, and is, in growth and habit, much like the old double flowering Almond, except that it is rather more hardy. It was brought to this country in 1857, and is easily propagated by layers or cuttings which will bloom the following season, though the full growth of the plant—about three feet—is attained for several years. *Deutzia gracilis* is a yet more diminutive shrub, bearing clusters of bell-like flowers of the most exquisite purity. It is generally considered hardy, though I have known it to be winter killed in exposed situations. *Deutzia scabra*, which is taller and bears larger flowers, is more tender and never survives one of our winters without protection. Both varieties are well worthy of cultivation. No amateur should be without one or more of the varieties of *Tamarisk*. Its delicate foliage and fine clustering purple flowers are alike beautiful. It thrives better if tied up with straw or evergreens during the winter months, but even if this precaution be neglected, and the top killed, the roots always send up new shoots in the Spring, which bear flowers the same year. The best variety (*Tamarix centralis*) blooms in August and should in every collection however small. *T. Africana* is a plant almost precisely similar in appearance, but blooms in May. The *Weigelia Sinensis* and *W. Coraensis* are comparatively new; the former is perfectly hardy and in June bears a profusion of beautiful pink flowers without fragrance; the latter is a little tender, but amply repays the slight additional care it requires, by its two abundant offerings of pink satin-like blossoms, one in June, and the other in August, or early in September. The different varieties of Japan Quince (*Cydonia Japonica*), white, blue, pink and brilliant scarlet are among the earliest blooming shrubs, the scarlet being particularly valuable at a season when gay flowers are comparatively rare. All the above thrive in any light rich garden soil, with a good supply of sun and air. Many more plants of this class thrust their pretty faces before me while I write, but my rapidly decreasing space warns me to pass on to the next division. I will, however, linger to mention the *Rhododendron Catawbiense*. When placed where it is sheltered from North winds and partially shaded, in a good peaty soil, nothing can

exceed it in attractiveness. Its dark glossy evergreen leaves, which challenge admiration every month in the year, are in June crowned with panicles of the most exquisite bloom—full, firm flowers of a blush white, tinged and shaded with delicate pink like an apple-blossom. By all means have a Rhododendron. You may gradually add to your collection, as they come under your notice, some of the many shrubs having equal claims with those recommended, but the mention of which I must omit.

HERBACEOUS PERENNIALS, ETC.

Many of the old herbaceous perennials have coarse muddy flowers which it is hardly worth while to cultivate, now that we have so many new and beautiful varieties at our command. At the same time, many of the older kinds must always be admired for their intrinsic beauty, however foolishly passed by and forgotten in the rage for novelties. Among the herbaceous Spireas, those commonly known as the King and Queen of the Meadow (*Spiræa ariæfolia*, and *S. lobata*) are abundantly worthy of attention. They send up yearly a strong, almost woody stem growth, bearing light graceful plumes of pink or white flowers, are in full glory in July, and their long duration of bloom gives them a double claim to our notice. Their foliage is also very desirable for cutting, and may, at a little distance, an effect much like that of geranium leaves. *S. Japonica* is a plant of smaller, more delicate growth bearing a fine white flower very desirable for cutting. *Alyssum saxatile* is a low growing hardy plant, which sends up a profusion of bright yellow blossoms in May or early in June. As its time of blooming is so early, it is better to plant the seeds in the Fall, in order to secure a good supply of flowers. It may be transplanted with great care, but it is better to plant it where it is intended to remain; always remembering, in the case of all seedlings, to thin out the young plants as soon as they are an inch high, that they may not be cramped by crowding. The same rules for treatment will apply to the different varieties of *Lychnis*, Columbine, *Rudbeckia*, *Campanula*, and almost all seedling perennials.

Dicentra Spectabilis is a native of Japan, introduced here within a few years. It has a tuberous root, sending up slender drooping stems in June and July, hung with curiously beautiful crimson flowers, relieved by two little protruding white wings, which add much to its grace and beauty. Like all perennials, it will take care of itself when once established, only requiring to be lifted and divided from the crown once in two or three years. As after its time of blooming is over, the leaves and stems turn yellow and die, it is well to plant some tall growing annuals in such a position as to hide it from the principal points of view after the first of July.

The Day Lily (Hemerocallis), as its name indicates, lives all its short life in one day, but as each stem bears a succession of flowers, this is not an objection. The blossom is exceedingly delicate and beautiful, and is never more attractive than when it first opens its fragrant cup in the soft mist of an August morning. There are three varieties in cultivation: *H. Japonica*, pure white, *H. Cerulea*, blue, and *H. flava*, lemon color. The last is less generally known, though by no means less beautiful than the others. As this plant is rather delicate, a covering of leaves or straw is necessary for the winter months.

Yucca.—There are several varieties of the Yucca, most of which are quite tender—some even requiring the warmth of a green-house. *Y. filamentosa*, is, however, one of the hardiest plants in cultivation. No amount of exposure can kill it. The root is strong and tuberous, and the foliage, which is not particularly graceful, is evergreen. Tall stems, tasseled with a profusion of white bell-shaped flowers, shoot up from the root in July.

The *Mexican Heliotrope* is a perfectly hardy plant, easily raised from seed, and bears long branching stems of pendulous blue flowers in August. It has a peculiar delicacy of growth, which makes it very attractive. [We do not know the "Mexican Heliotrope;" the common Heliotrope turns black after a slight touch of frost.—*Ed.*]

The *Forget-me-not* (Myosotis palustris) should, by all means, have a corner devoted to it. The plant is covered in June and July with a profusion of exquisite little clusters of flowers, which are either blue of different shades or white with a yellow eye. The best varieties are: *Myosotis alpestris*, blue; *M. alba*, white, and *M. azurea major*, deep blue, and large. They are easily raised from seed, and if started early will bloom the first season. The plants do better if removed to a new place every year or two.

Pinks.—Of all the varities of *Dianthus* none can equal the superb *D. Laciniatus* (or Heddewig's pink) introduced by Mr. Heddewig from Japan. It is perfectly hardy, though many persons imagine that it is not. [Ours died after blooming and perfecting seed.—*Ed.*] A slight protection through the winter months can do no harm, but, that the plants will thrive and bear a profusion of flowers without it has been abundantly proved. Authorities differ as to their powers of duration; some maintaining that they are perennial, while others class them with biennials. As my own plants will not be two years old until Spring I can not speak positively on this point. The young seedlings will, if planted very early in a hot-bed, bear flowers the first year, and the second, you may look for them in luxuriant abundance. The blooms are three inches in diameter, single or semi-double, and of various colors—some deep maroon crimson, some beautifully striped and marbled, and others pure white. They should be in every collection. A few of the varieties of *Caprationa* and *Picotees* are also quite indispensable. Though only half hardy, they may be successfully cultivated in the garden with slight winter protection. They may be raised from seed, but the seedlings are so uncertain, often bearing small single flowers, it is better to buy plants or cuttings of named varieties. All plants of this class require shade and moisture. Sweet William (*Dianthus barbatus*), is a biennial, the finer kinds of which are always desirable. *Antirrhinum* or Snapdragon is another biennial which no garden should be without. Of the named varieties the finest is *A. speciosum*, pure white and crimson. The best way of raising them, however, is to plant a paper of mixed seeds. If the young growth is made in a hot-bed, flowers will be abundant the first season. A covering of straw or leaves is advantageous for the winter. The same treatment is suited to *Ipomopsis elegans*, a biennial bearing delicate foliage and clusters of bright scarlet blossoms on the end of the stem. *Pentstemon* though often classed as perennials, seldom live over the second year. The varieties in cultivation are very numerous. They require an exceedingly rich soil, and shade and moisture are essential. An occasional watering with guano water when the plants begin to grow the second Spring, will make large and abundant flowers. The Pansy bed should be strewed with stable litter during the cold weather.

ANNUALS.

It would require a separate article to enumerate and describe, even partially, the hundreds of flowers of this class, which fill so important a place in the months of July and August, after the bloom of perennials has passed by. It will be sufficient for the present purpose to divide them into two classes, *hardy* and *tender*. The hardy kinds may be sown in the open ground in Spring, or even in the Fall; while the more tender ones must either have the aid of a hot-bed to bring them forward, or must be sown so late as to render their time of flowering extremely short. Among all the kinds introduced within a few years, there is none more valuable than the *Double Zinnia*, a native of the East Indies, and cultivated here as a tender annual. Plant the seeds in a hot-bed about the first of April, and remove the young plants to the border the latter part of May, and, when a few inches apart. As soon as the blossoms appear, a portion of them will prove to be single, and as these are generally worthless, the sooner the plants bearing them are uprooted the better. Those left will fill up the vacant spaces, as when their full growth is attained, they are from two to three feet high, and their long spreading branches make a diameter of from twelve to eighteen inches. In a light rich soil, they bear a succession of flowers till frost, and make a very pretty, though of course very slight, temporary hedge. The flowers are beautifully of a fine deep rose-color, very double and regular, looking, at a little distance, like small evenly developed roses.

Among the smaller annuals, *Alyssum maritimum* (white) receives a good share of favor. It grows near the ground, and is a very free and constant blooomer—two peculiarities which make it desirable for edging and small masses. Somewhat similar, though larger and bearing finer flowers, is Candytuft (*Iberis*). *I. amara*, white, and *I. speciosa*, deep purple, are the best varieties. They are quite hardy. The Tassel-flower or *Cacalia* bears an exceedingly delicate and pretty blossom. It does tolerably well planted in the open ground, but if small plants are raised in a hot-bed early in the season, and transplanted to any sunny spot in the garden, an early and continuous bloom will be secured. The seeds mature very rapidly, and by the time the plants of the first set have passed their prime, new ones, self-sown, will be ready to bloom. After the old plants have borne their last blossom, they should be removed. The foliage grows in a thick cluster close to the ground, from the center of which a slender waving stem shoots up, bearing delicate tassel-like blossoms. *C. coccinea*, red, and *C. sonchifolia* (or *aurea*), yellow, are the only varieties of which I have any knowledge.

The *Schizanthus* is an exceedingly beautiful annual, not by any means as extensively known or cultivated as it deserves. The flowers are of various colors, delicately veined and spotted, and nestle in a foliage correspondingly beautiful. *S. Hookerii*, crimson and yellow; *S. albus*, white and crimson, and *S. gracilis*, are the best varieties. It is a little tender, but may be successfully grown without artificial aid, if planted in a warm, sunny spot. It looks well grown in masses. *Euphorbia variegata* bears a little white flower, insignificant in itself, but from the manner of its growth, and the peculiar green and white foliage with which it is surrounded, it is prized by all lovers of flowers. The seeds should be planted several inches apart, as they send up strong fleshy growing plants about eighteen inches high, which are showy without being coarse, and not only an ornament to the garden, but very valuable for cutting. Its arrange with other flowers of more decided coloring. An annual quite indispensable to every collection, large or small, is *Eschscholtzia crocea*. It is a native of California but has proved perfectly hardy here. From May until hard frost, it is crowded with brilliant yellow blossoms, which look like so many butterflies. The foliage is beautifully light and airy. The seeds sow themselves in the Fall, and a mass once established will need no further attention except thinning out the young plants when they come up too thickly in the Spring. *E. alba* is a part of precisely similar appearance and habit, except that the flowers are white. Its long tap root renders it difficult to transplant. A few green-house plants such as *Ageratum*, *Stevia*, *Mimulus* and *Gillyflower* may be successfully raised as tender annuals.

BEDDING PLANTS.

Among the numerous bedding plants which make the garden gay during the later Summer months the *Verbena* presents the first claim to attention. It is too well known to require any description. Some of the finest varieties are: Lady in White, pure white; Defiance and Mrs. Woodworth, bright scarlet; Lord Raglan, pink with white eye; Lady Palmerston, purple with white eye, and Sir J. Paxton, crimson. They thrive best in a light sandy soil, and exposed to a hot sun. *Geraniums*, from their constant and brilliant bloom, are highly ornamental. The old Rose has the best foliage. Of scarlet Geraniums, Punch and Tom Thumb are indisputably the best; and in the same family, Luceda Rosea, bright pink, and Mary Weld, salmon color, are both desirable. No fancy geraniums are more valuable for bedding than Perfection and Pretty Polly. *Heliotropes*, too, fill an important place from July to September. Lady Helen Mar and Splendidum, both dark and free bloomers, are excellent varieties. For light flowers, nothing is better than the old Peruvian. *Salvia* or *Flowering Sage*, is exceedingly ornamental in the garden, sending up brilliant spikes of flowers in August. *S. coccinea*, intense scarlet, and *S. amabalis*, blue, are the best varieties.

Some moist sheltered spot must be given to the *Fuchsia*, an exceedingly beautiful and graceful flower, with innumerable varieties. The most perfect specimen of all is the *F. speciosa*, dark blue and red. The Hero, which bears lighter colored flowers, is also a fast grower and very free bloomer. The Empress, white and rose, the Venus de Medicis, pink, the Climax, deep red and purple, are also fine, and have that cool limpid coloring, absolutely refreshing to behold, which belongs exclusively to flowers grown in the shade. *Cupheas*, *Bouvardias*, *Lantanas*, *Coral Plants*, and many others, bloom abundantly in the open ground. The tender, summer-flowering bulbs give us a most gorgeous array of blossoms late in the season. Among these the *Gladiolus* stands pre-eminent, as its tall stems hold up the inimitable flowers to the sun. The Hector, bright rose, the Mad. Leseble, white, the Joan d'Arc, bright purple, the Adonis, cherry color, are among the best. These flowers have a proud magnificent beauty, and never fail to elicit admiration. *Amarillis Formosissima* gives us large superb lilies in July or August, on stems about ten inches high. The flowers are a rich velvety crimson, spotted with gold. *Tigridia pavonia* bears very showy and beautiful flowers of a somewhat similar character, but without the spots. The *Tuberose* bears tall spikes of creamy white flowers, which are deliciously fragrant. The first growth must be made under glass, and it is quite useless to preserve the bulbs for a second season, as our sun is not hot enough to ripen them fully. A few bulbs may be reserved, and planted a week or two after the first set, for a succession of bloom.

There are numerous *climbing plants*, all worthy of attention. Roses in endless variety—Dahlias by hundreds, and Chrysanthemums by the score—but each one of these demands a separate article. Any one, however, who will plant all the varieties of flowers herein enumerated, or who will select a few from each division, and add a half dozen Roses, may secure a succession of choice and beautiful flowers from the time the Spring snows melt away, until winter winds make sharp suggestions of some other employment than gardening. It is wiser to have some personal knowledge of a plant before setting it in your own garden. If possible, know something of each one before you admit it to your collection; then give it a reasonable amount of careful culture, and success will not fail to crown your efforts. [But when not practicable to first study the flowers on the grounds of others, your own garden will furnish the school.—*Ed.*]

A Few Convenient Garden Tools.

An old gardener always uses fewer and simpler tools, and does better work, than the novice. We will describe a few of the best, indeed about all that are essential for common operations. A small outlay will purchase the whole of them, and the facility they give to garden work, will pay a very large interest on the cost. Let it be remembered, that a good implement, however high the price, is in the end cheaper than a poor one costing not a fourth as much. Light, well made garden tools, of cast steel, or spring steel, or of iron edged with steel, are always to be preferred to those made wholly of iron. The former do not bend or batter, or break so easily; they cost a little more, but last much longer, do not rust readily, keep sharper, and are lighter and handier in every respect.

THE SPADE is necessary to dig holes, drains, etc., to cut turf, to move small quantities of earth in making beds, etc., to divide masses of shrubs or other plants, to take up trees, and the like, but it no longer holds the place of honor.

THE SPADING FORK, (fig. 1,) is the usurper. This is *the* implement for working the soil. It penetrates the ground with greater ease, and lifts as much soil as the spade, leaving it light and crumbly, not in soggy lumps. We prefer a five tined fork, the tines bevel-backed, of the best steel, and gradually and very slightly increasing in width from the tread to the points, so as to prevent stones from catching between them. For moving loose earth, sand, compost, etc., a *shovel* is indispensable, except in very small gardens. So also is a common field *hoe*.

Fig. 1.

THE REEL AND LINE, (fig. 2,) of the form shown in our cut, is most convenient, but any cord wound upon a pointed stake, with another short stake attached to the end, will answer the purpose well. A strong cord of good size is preferable to a string. It should be strong enough to bear a hard pull. The garden line serves a more important purpose in giving a garden that symmetry and regularity which marks a well kept place, than any other implement. A long line made so strong as to bear stretching, yet so small in diameter as not to be swayed by the wind, is preferable. It should be housed at night away from dews.

Fig. 2.

THE EDGING KNIFE, (fig 3.) Good grass sods are far preferable to the box plant as edgings for beds. The former, neatly cut and laid, and kept closely trimmed, are neater, more pleasing to the eye, and can be more readily "mended," than the box which often winter kills or fades in spots, and requires a year or two to acquire a respectable size. The grass edging can be in perfection in a month or two. To clip and trim the edges of the sod border, a half-moon shaped blade, with a handle like a spade, is convenient, but not indispensable; a sharpened spade is a good substitute.

Fig. 3.

A STEEL-TOOTHED RAKE, the head and teeth being all spring steel, and in one piece, 8 to 12 inches wide, with the teeth long and well annealed so as not to bend easily, is essential for nice working of the soil, for pulverizing it, for mingling compost with the surface, and for dressing ground walks, removing stones, lumps, etc.

A GRASS RAKE (fig. 4,) is one of the most convenient tools we have used. It is simply a hay rake, with at least twice as many teeth as the common hay rake. The teeth are shorter, and of course closer together. This gathers up the clippings of the grass plot or lawn very clean. We do not make hay in the garden, and the grass never should be more than 4 inches high. All that this rake will not gather, is best left on the sward as a mulch for the roots; it will not show, perceptibly.

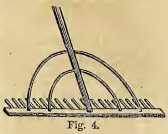

Fig. 4.

THE SHUFFLE HOE, (fig. 5,) often wrongly called "scuffle hoe," is a very convenient implement for working among plants. If provided with a long handle, it saves the back from many an ache, and some wear of fingers. The blade should have both edges sharp, and then in *shuffling* it backward and forward, it cuts both ways, severing the weeds, and leaving them on the surface, and lightening the soil. We advise its general adoption.

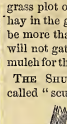

Fig. 5.

DIBBLES, (fig. 6,) of which we present two kinds, are simply round pointed pieces of wood or iron for making holes in which to set out plants or cuttings rapidly. But we do not advise their use in general, for though convenient, a much better hole is made with a trowel or flat stick, inserted and pressed to one side; the soil is not then compressed on all sides. Still the dibbles are very convenient in rapid work, and in the field. The spur on the long one regulates the depth to which it may be thrust.

Fig. 6.

THE GARDEN TROWEL, (fig. 7,) is very convenient for lifting and transplanting, digging holes, etc. It is like a common small mortar trowel, with the sides curved upwards a little. Our American made garden trowels are less curved than the English manufactured ones, which form nearly or quite half a cylinder; the former are preferable, as they do not cling to the soil, while they answer all purposes.

Fig. 7.

A KNIFE-BLADE TROWEL or weeder, (fig. 8,) was recently shown to us by Mr. Theodore Holt, a gardener of this city, now a missionary horticulturist at Port Royal, S. C. It consists of a blade of steel, an inch and a half wide, and 6½ inches long, tapering with a gradual curve to a point, the shank raised at right angles to the blade, which is sharp at both edges, and nearly flat on the upper side. The use of the implement is in weeding, and thinning out all kinds of vegetables and other plants sowed in rows, and one a little familiar with it, does this tedious work with ease and rapidity.

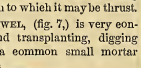

Fig. 8.

THE SPUD, (fig. 9,) is a stout chisel upon the end of a cane. It should be in the gardener's or master's hand whenever he walks through his grounds; and wherever a weed of any considerable size shows itself, the spud should seek out its root, deep down under the sod or spreading close to the surface, and cutting it off, leave the plant to wither where it stood, or to be easily pulled up. This is good for thistles.

Fig. 9.

THE WEEDING FORK, (fig. 10,) is a little implement, which we have taken great satisfaction in using of late years. It is the spading fork on a one-hand scale. Penetrating the soil about four inches, it loosens it thoroughly near the roots of plants, and in places where the spading fork can not be used. At the same time it greatly facilitates the uprooting of weeds. For working strawberry beds it is a most excellent implement.

Fig. 10.

BAYONET OR ONION HOE, (fig. 11.) This is a sharp-pointed, double edged steel implement, about 8 inches long and 1¼ inches wide at the broadest part, tapering down to a point. It is set like a common hoe, upon a handle 4 or 4½ feet long. We use it *more than any other garden implement*. The point turned to either side, is convenient for working among all kinds of plants, and for digging drills, loosening up the ground, etc. The long edge answers the purpose of the common hoe for cutting weeds, loosening the soil without heaping it up, etc. Mr. Holt's trowel, (fig. 8,) with the shank curved so as to bring the middle of the blade in front of a long handle, and three inches distant, would be still better than the bayonet hoe, we think.

Fig. 11.

Earliness of Grapes.

At a meeting of Fruit Growers in Rochester, last Fall, Mr. Barry spoke of the Rebecca grape as "a high flavored grape, as good as a fine Muscat." Mr. Hoag regarded it as "a very superior grape," etc., etc. We agree with these gentlemen, thus far; but when they speak of it as ripening much earlier than the Diana, we can not accord with them. In our experience, it is *eatable* a little earlier, but it does not get its juices matured and perfected so as to be really ripe and delicious until the Diana is fit to be gathered into the same basket. The longer it hangs upon the vine without exposure to hard frosts, the better. Two baskets of them lie on our table now as we write, (Jan. 10th,); those cut early, have a green, watery look, as if imperfectly ripened; those cut later, have a golden, semi-transparent, sunny aspect, and they are much sweeter than the others.—There are several new grapes, of which we hoped to hear more last Fall, and among them the *Cuyahoga* and *Crevelling*. (The Crevelling is called by some "Catawissa," by others "Bloom.") So far as we have heard, little new testimony has been given to their excellence. Those who advertise these and other novelties, should have brought the fruit before our various Pomological Societies and Fairs, last Fall, and obtained their impartial opinions. If the propagators can not get a favorable verdict for their fruit from such sources, the probability is that it is not worthy of public notice. If they can, this favorable judgment will be worth a hundred fold more to the vender than the most flaming advertisements or the loud puffings of interested persons. We suspect, however, that the two grapes above mentioned are worthy of all the commendation that has been bestowed on them. They are both superior to the Hartford Prolific and Con-

cord, and they ripen earlier than the Isabella.

The *Adirondac* grape, which hails from Plattsburg, is said to ripen a fortnight before the Isabella, and to be of first-rate quality. Its ripening last Fall at Plattsburgh, and its exhibition at Montreal in the month of October, is good evidence of its early maturity. If it will ripen at Plattsburg, before hard frost, it will ripen any where in the United States. Its *earliness* being proved, now give us good proofs of its *quality*.

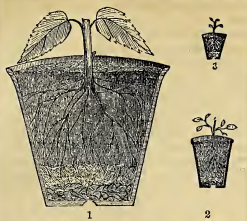
Some time last Fall, Mr. Thomas, of the Country Gentleman, writing from Ohio, mentioned visiting a *Seedling Isabella*, which was fully equal in flavor, size, etc., to its parent, and two weeks earlier. If these facts prove to be *facts*, the public will want to hear more about that grape. For, let men say what they will about the Delaware, Concord and the other new comers, we pray take not away from us the old Isabella where it can be ripened. And if this seedling is fully equal to it, and ripens a fortnight earlier, it will be hailed with delight.

How to Treat Dwarf Pears.

I have them fifteen years old in my garden, thrifty, hardy, productive, and bidding as fair to live the next fifty years, as any standard tree upon my grounds. The complaint against these pets of the garden, I am fully persuaded, is owing more to neglect, and mismanagement, than to any inherent difficulty. Some varieties will not flourish on the quince stock. The fruit books will point them out. Do not plant such. They will not be productive on grass ground, or in hard inflexible soil. Do not plant them there. They want a deep, rich, mellow border, at least eighteen inches in depth. If you can not afford to prepare a border, do not purchase dwarf pear trees. In addition to being properly planted, they must have care every season. Now they should be shortened in, about two-thirds of the last season's growth. This keeps them stocky, and prepares them to sustain a great burden of fruit. They also want a barrow full of stable manure put around them every Fall. The quince roots can not go far in search of food. They should have all they can take up within six or eight feet of the tree. With manure and good management dwarf pears will be a success. C.

Plant an Apple Orchard.

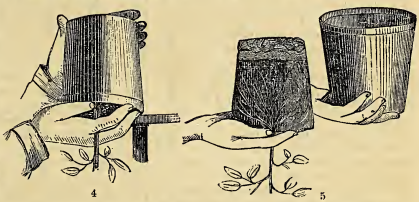
The old ones are fast dying out all through the older States. They were planted a hundred years ago, or more, have done good service, and ought to have their day. When apples are $3 a barrel and upward, there is not an adequate supply in the country. They can be grown at a dollar a barrel, with profit. The apple crop in a single small county in this State, was worth half a million of dollars last year. Other counties, in the older parts of the Eastern States, were under the necessity of paying out a hundred thousand dollars for this fruit, because they had not the article at home. Peaches and plums we may be able to get along without, but apples we must have—for sauce, for pies, for the dessert, and for the dinner basket of little boys and girls who can not come home from school to dine. We say then to every farmer, plant an orchard of at least a hundred trees. The trees are all ready for you in the nursery, well grown, and grafted, two and three years from the bud. Get thrifty trees, of varieties that you know will flourish in *your* locality, and in four years you will be eating fruit from them. Do not fail to plant an orchard this very month.



1 2 3

Earthern Pots for Plants—Very Useful for Everybody

Comparatively few persons, except those who have green-houses, have yet learned the decided advantage there is in having an assortment of earthern-ware pots about the garden. They cost but a trifle—only about a dollar for a hundred of the smallest size, and from that up to five or six dollars per hundred for the largest size needed in ordinary gardens; and they will generally pay for themselves the first year, while they will last many years if used with moderate care. Take, for example, the operations in a common vegetable-garden on the farm, or in the village lot. We must wait until the ground is dry and warm, before the work of preparation, and seed sowing can begin, and the Summer is half gone before the table is supplied with anything more than a little lettuce, a few radishes, and, perhaps, some early peas. Asparagus and pie-plant, where these are grown, about complete the assortment. But by simply providing a few pots, the lettuce can be had *much earlier*, so can the melons, the onions, the cabbage and tomato plants, the cucumbers, the squashes, and a dozen other things, and with more certainty, and but little more labor.



4 5

The flower garden, too, may be a bloom of beauty and a source of pleasure, many more weeks. Having on hand the flower pot, or plant pots, as we may call them, we can sow our seeds a month or more in advance, and have the plants all in vigorous growth by the time the ground is warm and ready to receive them. Ten, twenty, fifty, or a hundred pots of earth may be sown with seeds at an early date, and be set on the sunny side of the house or barn, or of a board fence, during the day, and over night also, except when the chilly air betokens a frost. They can then be readily set into the barn, or into the cellar if very cold, or they may be covered with blankets, carpets, mats, or hay, or straw. A hundred 5-inch pots will scarcely require a space five feet square. After the seed is sown, an occasional watering is required—using water with the chill taken off, putting it on moderately—not in a flood—with a common sprinkler. The pots may be filled with earth and the seeds sown under cover on rainy days, if a mass of soil has been previously prepared and placed under cover. (For description of best soils, and best kinds of pots, see the *March American Agriculturist*, page 71.) If one has plenty of small pots, a seed or two may be sown in each, and one plant only be allowed to grow. At the proper time the soil can be slipped out in a moment and set into the ground; the plant will grow right on, and be in a bearing condition, when perhaps the seed sown in the open soil is just beginning to start up, if perchance it has not been rotted by a long cold rain. An hour's labor upon the pots will provide two or three dozen cucumber or squash plants, which when planted out will start off ahead of all the noxious insects. It is usually preferable, however, to sow more seed in larger pots and after the plants are grown so as to begin to crowd, transplant them into smaller pots, one or two in each. Four, six, eight, or more small plants, like cabbages, may be left in each pot of larger size, and the soil be divided when putting out; but we prefer smaller pots with one plant in each, at the time of the final transplanting. There is then no breaking or disturbing of the roots in the removal.

Figs. 1, 2, 3, are *sections* of different sized pots filled and with plants growing. In the bottom are pieces of broken pots, or bricks, stone chips, or oyster shells, to afford free drainage off through the hole in the bottom, for any surplus water. It is important to have only so much moisture as will be naturally retained by the soil. Above the bottom layer is half an inch or so of moss to sustain the earth. Thin sods, or fine shavings may be used, in the absence of moss. The drainage and moss will occupy one-fifth to one-fourth of the pot (it is shown too thick in the engravings,) and the soil be filled in to within half an inch or less of the top.

Figures 4 and 5, show the mode of taking out the plants. Place the hand upon the soil (fig. 4) with the stem between the fingers, invert the pot, and strike its edge gently upon the corner of a table, block, or other wood. The mass will slip out as seen in fig. 5. After a little practice it will be a pleasure to often take out the soil and examine its condition, its dryness or wetness, and the growth of the roots. If these have filled up the soil, and appear crowded, before the open ground is ready, transfer them to larger pots (called "repotting.") Indeed most plants are benefited by one, two or three transfers; they grow more stocky above and in the soil, and a stronger mass of roots is secured. To repot, take a pot one or two sizes larger; put in the drainage and moss, and enough soil to raise the inserted ball of earth nearly to the top. Remove the bits of crockery from the bottom, and loosen the roots a little if in a compact mass; set the ball in and sprinkle in loose earth around the outside, packing it down gently with the fingers; water moderately, and set aside. The roots will soon spread out into the larger space, and be ready for a still larger pot, or for planting out. The whole process is simple, and easily performed after a little experience, and will afford real pleasure. Take our advice, and order

a few pots this season to begin with, from the nearest pottery, or seed-store, or agricultural warehouse. We also advise the pottery men, and seed and implement dealers, to provide an ample supply by another season, if not this, for we hope to have tens of thousands in use in the *Agriculturist* gardens all over the country.

The Tuberose—Very Desirable.

On few flowers has nature lavished more attractions than upon the Tuberose (*Polyanthes tuberosa*). Graceful and beautiful, whether we regard the full clustered spike or the individual flowers, of a delicate, rich blush, or nearly white, it diffuses far and wide a fragrance not less delicious than powerful, and not in the least cloying. As its name indicates it is a tuberous plant. It is a native of Ceylon, and requires a long season. The time is at hand for planting the tubers, and most important is it to secure good roots. They are annually imported by our seedsmen, and are besides grown in large quantities by florists in the vicinity of New-York, and other cities further South. A good bulb is large, plump and firm, with very few offsets; one or two small offsets are not objectionable, as they help to furnish foliage; but bulbs with any considerable number should be rejected, as the chances are that the main bulbs bloomed the previous season, and will not again, as the bulb never blooms but once. Plant them in rich and moderately dry soil, about one foot apart, covering the top of the bulb about one inch. So soon as the flower stalks appear, set by each a strong stake, four feet long (one foot in the ground,) to which tie the brittle stalk as often as necessary to keep it from being broken. Where the seasons are not long enough to allow the plant to perfect all its flowers or bulbs, about last of March or first of April put single bulbs into four inch pots, in soil composed of equal parts of loam, sand, and rotten manure. Give but little water and place in some warm part of a room or under the stage of a green house until they form roots, which will usually be in about two weeks. They should then be placed where they will be fully exposed to the light, in a temperature not lower than 55° or 60°; when the weather is warm and settled they may be turned out into the open ground, being careful not to break the ball of earth around their roots. They bloom in August and September.

So soon as frost kills the leaves in the Fall take up the roots and spread them out in the sun to dry, covering them at night, or bring them indoors to avoid wet or frost. When they are so dry that all the soil will readily separate from the tubers, remove those that have not bloomed, put them aside for blooming plants next season, and keep the others to propagate from. The leaves and roots should then be cut off and the bulbs put away in the *dryest* place possible—if where the temperature will be from 60° to 80° through the Winter, so much the better. Tubers that have bloomed should have their largest offsets taken off the next season and planted to make blooming bulbs for the succeeding year, while the old bulbs are planted to produce more offsets.

THE HOUSEHOLD.

Drying Woolen Stockings.

All housekeepers know how difficult it is to wash and dry woolen hose without having them shrink. The strong feet of adults can overcome the shrinkage, but for the tender feet of children and infants the difficulty is a serious one. It can be easily avoided, however, by a simple method, which may not be known to all the readers of this department of the *American Agriculturist*. When the stockings are new, lay them flat upon a piece of paste-board, mark out the form with a pencil, and then cut the board pattern fully as large as marked. When the stockings are washed and ready for drying, put one of these patterns into each, pinning them over the top, and they will remain of the original size after being dried. The sides of glove or ribbon boxes, or other paper boxes, make good dryers. We happened in at a house the other day, where there were about half a score of children, old and young, and the rows of some thirty stockings on stretchers, set up to dry, was a pleasant sight, and suggestive—they suggested this paragraph. One thing more. In the case alluded to, the "good man of the house" had provided neat wooden stretchers, apparently whittled out of shingles with a jack-knife, on some winter evening. (He doubtless deserved to have such a fine group of children—they appeared to be well-behaved ones.) We indulged our fancy in imagining how the stockings for the tiny feet, then in the cradle, would successively occupy a place on the different sized stretchers that stood in that long row, the bottoms ranging from two or three inches in length, to a full grown *foot*.

Contributed to the American Agriculturist.

Substitutes for Coffee.

1—E. C. Long, of Erie County, N. Y., sends to the *Agriculturist* the following directions, which are the result of several successive experiments to obtain a good substitute for coffee: "Take clean *rye*, boil it in water ten minutes, dry it in pans, and browu it the same as coffee, taking care not to burn it. Then peel some carrots, cut them in small square pieces, dry, and brown them the same as the rye. Grind both the rye and the carrots, and mix one part of the carrots with two parts of the rye. A tablespoonful of the mixture makes a quart of an agreeable drink—an excellent substitute for coffee, we think.... I have heard that beets are good, if prepared and used the same as above described for carrots, but have not experimented with them."

2—Adam Bohn, of Carroll County, Ill., writes that the *Nepaul Barley*, (No. 190 in our Seed list,) is one of the best substitutes for coffee in the country. "Scald or boil it for a few minutes; dry, and browu it. A little Rio Coffee added makes it very pleasant, so much so that some of the oldest coffee drinkers have mistaken it for the pure Rio. An old lady tells me that since adopting the above drink, she has not been afflicted with her former headache, which was so troublesome."

3—O. R. Tisdel, Stephenson County, Ill., writes: Take common garden *carrots*, wash, slice in say ¼ inch pieces; cut across, leaving the pieces about the size of kernels of corn; dry on tins in an oven about 24 hours, then brown and grind the same as other coffee. Use this with one-fourth part or less of Rio or Java coffee, and a rich excellent coffee is made, requiring a good judge to distinguish it from the pure article. It should not be made too strong.

4—W. B., of Oletha, Kansas, writes: We have tried for coffee making, wheat, barley, corn, broom seed, sórghum seed, dourah corn, potatoes, acorns, carrots, parsneps, hickory nuts, and okra, and could only drink three or four of them. Nothing pleases us so much as *dandelion root*, dried and lightly scorched, but never burned. We esteem it a stimulant, tonic in its influence, healthful, and as agreeable to the taste as the pure coffee berry. [This is one of the recipes advertised by some of the *humbug* "Professors" as a 50-cent secret. As a medicinal drink, when needed, a little dandelion root is not objectionable. The U. S. Dispensatory says it is slightly tonic, diuretic and aperient.... is thought to have a specific action upon the liver, and is applicable to derangement of the digestive organs. This is as a medicine. It should *not* be used when there is an irritable condition of the stomach and bowels.—ED.]

5—Wm. Muir, of Lawrence County, Ind., recommends *sweet potatoes;* cut in thin slices, dry in sun or in an oven, and put away until wanted. Pareb say a pint at a time, like coffee, and for a meal for six persons, grind and use about ¼ teacupful. It gives a clear fluid. A bushel of sweet potatoes will supply a family of six, old and young.

6—H. Baster, of Gates Mills, recommends "equal weights of *chicory* and coffee, dried and roasted in the usual manner. The chicory root is raised as easily as carrots, and in exactly the same manner. To prepare the root, wash it clean, slice lengthwise in 4 to 6 pieces, according to size, cut into ⅝ inch lengths, dry and keep in a dry place until wanted." [Chicory is largely used to adulterate coffee in this country, and especially in Europe, 25 million pounds being used in England and France alone. But its prolonged free use produces cramp in the stomach, heart-burn, loss of appetite, acidity, constipation or diarrhea, weakness of the limbs, tremblings and sleeplessness, cloudiness of the senses, etc. For full description of plant, with engraving, mode of cultivation, etc., see *American Agriculturist* for February, 1859—(vol. 18, page 53)—ED.]

7—Jairus Rich, Hamilton County, O., while approving economy in all business transactions, well suggests whether a true patriot will drop the use of coffee, *solely* on account of its extra expense, when all the extra price now paid (and a little more) goes directly to support the expenses of the country in these perilous times.

[REMARKS.—The taste for coffee is wholly an acquired one; nobody likes a *pure* coffee infusion until they learn to do so by long practice, first disguising the coffee taste with milk or cream and sugar. Pure water is always most agreeable to the natural taste. People would feel as well, and *be* quite as well, if coffee and tea were banished, and the saving would be immense. We confess to drinking coffee, but only when prepared thus: The cup ¼ full of home-produced cream; ½ full of *boiled* milk; plenty of sugar; the rest filled up with coffee of fair strength. Such a drink we can "worry down" without much wincing. Tea we have never learned to like, and are too old to begin.—ED.]

To Cook a Beef's Heart—By "Dolly."

[We continue to receive numerous "recipes" on this subject, most of which are somewhat similar to each other, and not materially different from those given last month, page 86, but we can only make room for the following rather amusing letter.—ED.]

To the Editor of the American Agriculturist.

Your just appeal in the February *Agriculturist* in favor of beeves' hearts as a nutritious and cheap food, appears to me to staud in a fair way to be uncultralized, if the directions given by correspondents be followed for cooking by any one expecting anything more palatable or savory than hashed sawdust, or boiled shavings.—Shade of Mrs. Glass to the rescue! "Gash it," says one; "soak it," says another; "boil it," say all. Chop it, mince it, fry it, stew it—effectually spoil it, and then wonder that no one will eat it. But give it the slightest chance, and, if English Hare be justly esteemed a delicacy, Beef Heart is not to be despised.

Don't "boil until tender;" it is tender—nothing more so, if from a well-conditioned animal. Don't "gash it," to let all the juice out—this is delicious, and wanted in the gravy; there are receptacles enough for the stuffing, which should be a simple veal stuffing, richer or plainer, as desired. Wash the heart well in warm water; fill all the tubes and holes with the stuffing, and also spread a deep layer over the top, or thick end of the heart; skewer the *flap* (which must be left on by the butcher) over the stuffing to keep it from falling out. Have the oven at a moderate heat, put in the heart, baste it frequently with butter, and let it *bake* steadily 1½ hours, if it weigh 6 lbs.; or ½ hour more or less for each pound over or under 6 lbs. When within the last quarter of being done, turn the melted butter and drippiugs out into a hot frying pan, return the heart to the oven to finish cooking, while you make the gravy, thus: Add ½ pint *boiling* water to the contents of the frying pan, also (divided into 4 parts) a piece of butter the size of a small egg, sprinkle with the dredger enough flour to thicken, and add salt and pepper to the taste. Set over the fire and stir the gravy until having simmered gradually, it boils, and is done. Put the heart on a *very hot* dish, (a water dish if you have

one) pour over it a little of the gravy, the remainder of which serve up in a *hot* covered butter boat. Have your vegetables ready to serve when the heart is *dished*, your plates *kissing hot*. Cut the heart (beginning at the thick end) in slices lengthwise, eat while hot, and you've a dinner fit for a President. And then, if there be any left from dinner, it makes a hash not inferior to, and much resembling, jugged hare....Be it remembered, that a beef heart chills as quickly as fat venison or mutton, and can not be *fully* appreciated unless eaten when direct from the oven, and on very hot plates.

DOLLY, THE COOK.

Cottage Farm, Dutchess Co., N. Y.

A Good Home-made Yeast.

Mrs. Jane E. Foote, of Onondaga County, N. Y., writes to the *American Agriculturist* thus: "A very nice yeast is made as follows: Peel and boil twelve potatoes; pour off the water, and jam fine. With ready boiling water from the tea-kettle, scald two quarts of sifted flour in a pan, making it about the consistency of thick paste. Add a teaspoonful of ginger, a tablespoonful of *salt*, and the potatoes before prepared, heating the whole well together. When *cool*, add four yeast cakes, previously dissolved in warm water, or a teacupful of hop-yeast. The above quantity will do for a "baking" of three loaves, *four times*, by keeping in a *cool* place. It has this advantage over the usual prescriptions for potato yeast, while answering about as well, viz: that it does not need to be made on every baking day.

Cocoanut Cakes—Cocoanut Jumbles.

Mrs. J. B., of Allentown, contributes the following to the *Agriculturist:* For *cake*, skin one cocoanut and grate fine; add 1 lb. sugar, 1 lb. flour, 1 teacupful milk, 1 lb. sugar, 8 eggs, and spice to the taste.——*For Jumbles:* 1 grated cocoanut, 1 teacupful flour, 1 teacupful butter, 2 teacupfuls sugar, and the whites of 3 eggs. Mix and drop them on baking tins, a little distance apart. They are very nice. [These are the same as are sold by the confectioners, we suppose. They are very good in the mouth, but not so in weak stomachs. We should hardly recommend them for children. Their digestibility depends much upon the fine grating of the cocoanut, unless they are finely masticated by good teeth, before swallowing. The amount of butter used, though perhaps necessary to their good keeping and oily taste, tends to render the cocoanut more indigestible.—ED.]

French Loaf Cake.—By same as above: 1 lb. flour, 1 lb. sugar, 1 lb. raisins, ¼ lb. butter, 1 cup new milk, 1 teaspoonful raisins, 5 eggs, and spice to taste.

A Truce to Corn Bread.

In addition to One Hundred different recipes already published this year, we have on hand nearly 200 others, and the number is increased by every mail. The subject is an important one, and we are glad to have aided to excite so much interest in it; but probably it will not be desirable to devote more space to the topic at present. We return thanks to the many kind contributors, and regret that we can not find room for all their favors. It is rather remarkable that among nearly three hundred recipes contributed for the *Agriculturist*, so few are just alike.—A CORRECTION: In condensing and printing so many recipes, from a variety of manuscripts, a few errors have doubtless occurred. Thus: in No. 32, page 54, (February,) & should be *f* in the word cooked, and read "....When sufficiently *cooled*, etc."—In No. 133, page 87 (March), read: "2 *teaspoonfuls* of salt, etc."

BUTTER IN WINTER.—We return thanks for several recently received communications on this subject, which will be reserved until the more appropriate season, next Winter.—Many good hints on other topics, received, are necessarily laid over.

A True Farmer-Soldier's Wife.

[Since the beginning of the present year, it has been our pleasure to receive about thirty thousand letters from subscribers in different parts of the country, and while mainly on business matters, they have contained very frequent incidental allusions that have afforded us no little pleasure. The historian could gather a true picture of the *feeling* of the country at the present peculiar period, from these offhand private business letters. As we omit the name and town, we violate no confidence in giving the following extract from a recent letter from Edgar County, Illinois, remarking that it is similar in spirit to very many others received, and shows the true character of multitudes of the daughters of the land, West as well as East.—ED.]

MR. EDITOR.—The fact that my husband has exchanged the plow for the sword, has prevented his renewing his subscription; but as I am the farmer now, I must still have the *American Agriculturist*, and I send you the very first dollar I have been able to spare for that purpose. My husband has chanced to receive no pay as yet, though six months in the service, and our farm produce only brings about half price; but we have abundant crops, good health, patriotic husbands, and firm hopes of still having *a country*. So we will "thank God and take courage."

The Editor with his Young Readers.

A Very Good Memory—Some Hints.

Mr. N. L. Wilcox, of Windsor, Ashtabula Co., O., writes to the *Agriculturist*, that Emma Sweet, 15 years of age, learned **2,087** verses in the Bible *during one week*. This is equivalent to 69½ chapters of 30 verses each. Or it is equivalent to all of Matthew (1,071 verses), all of Mark (678 verses), and to the 36th verse of the 7th chapter of Luke. It is equivalent to the whole of the Book of Genesis (1,533 verses), and over 20 chapters in Exodus..... Alvira Moore of the same town, learned in one week **1,515** verses, equivalent to nearly all of Matthew and Mark....Emma and Alvira should be very thankful for such good memories. We would give more than one thousand dollars to be able to learn half as many verses in the same time. Such a memory would save us much time and labor.

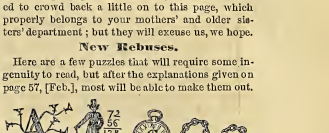
HOW TO IMPROVE THE MEMORY.

A few persons, like those above referred to, have a native faculty of remembering almost everything they read once or twice; but these are exceptions, and we doubt not, that should we ask each one of the hundreds of thousands of boys and girls who read the *Agriculturist*, "Have you a good memory?" ninety-nine in every hundred would answer, "no!" The truth is, almost everybody's memory is poor, until it is trained and cultivated, and the only way to improve it is by use. If a boy puts his arm in a sling, or keeps it hanging by his side, it will grow slim and weak. If, on the contrary, he use it vigorously, holding plow, chopping wood, and in other vigorous exercise, it will grow muscular and strong. The boy who goes into a blacksmith shop as an apprentice, strikes very feeble blows upon the heated iron, at first; he scarcely makes a visible impression. But after a few months' exercise, his blows tell; his arm has not only become strong, but also disciplined to give a proper direction to the blows. Just so with the memory. Exercising it in any direction will give it strength and disciplined power. One having a weak memory, should specially cultivate that faculty. Parents and teachers often make a great mistake; because a child exhibits a dislike of arithmetic, or of any other branch, they let him give more attention to something else, for which he appears to have a liking, or natural tact. The true plan is, to give most attention to the exercise and cultivation of those very faculties which are the weakest. In this way only can a well balanced effective mind be secured. This applies to the education up to maturity of mind and body. With this general discipline, the mind will afterwards act most effectively if its energies are mainly turned in some specific channel of thought.

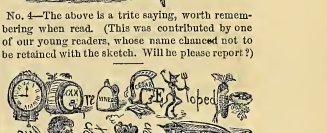
Crowded Again—The Maps.—The continued calls for maps of the scenes of the war operations, show that our readers, old and young, desire these *now*, more than anything else, and they prefer them in the *Agriculturist* to other papers, because our maps are so well printed, and on such good paper. We trust our younger readers are studying geography very rapidly and effectively now; if so, they will cheerfully wait longer for the problems, stories, etc., that would otherwise occupy page 121. As it is, we have ventured to crowd back a little on to this page, which properly belongs to your mothers' and older sisters' department; but they will excuse us, we hope.

New Rebuses.

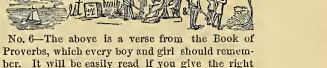
Here are a few puzzles that will require some ingenuity to read, but after the explanations given on page 57, [Feb.], most will be able to make them out.



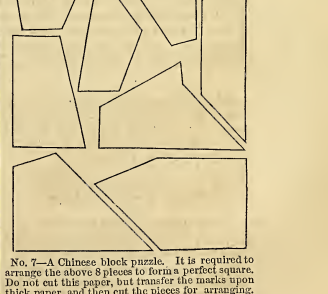
No. 4—The above is a trite saying, worth remembering when read. (This was contributed by one of our young readers, whose name chanced not to be retained with the sketch. Will he please report?)



No. 5—A political axiom, or truth, which is *not* being demonstrated in our country, just now. (Contributed by R. F. Roberts, Racine County, Wis.)



No. 6—The above is a verse from the Book of Proverbs, which every boy and girl should remember. It will be easily read if you give the right character to the men shooting the little birds.



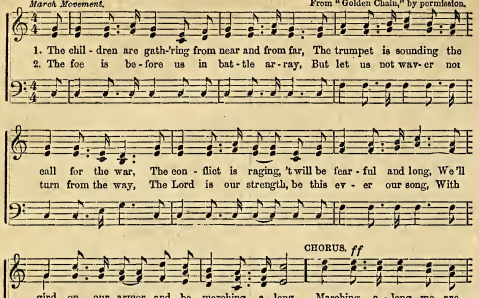
No. 7—A Chinese block puzzle. It is required to arrange the above 8 pieces to form a perfect square. Do not cut this paper, but transfer the marks upon thick paper, and then cut the pieces for arranging.

Answer to No. 2 in February *Agriculturist*, page 57: "*On earth peace, good will toward men.*"

Answer to No. 3, (same page): The Union must and shall be mummy; that is, "*The Union must and shall be preserved.*"

I.—MARCHING ALONG.

Words by R. P. CLARK. *March Movement.* WM. B. BRADBURY. From "Golden Chain," by permission.



3.

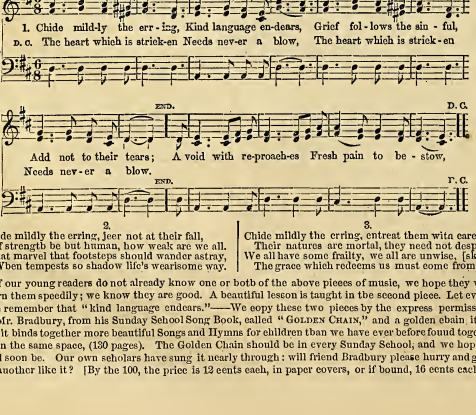
We've listed for life, and will camp on the field,
With Christ as our Captain we never will yield:
The "sword of the Spirit," both trusty and strong,
We'll hold in our hands as we're marching along.
Chorus.—Marching along, &c.

4.

Through conflicts and trials our crowns we must win,
For here we contend 'gainst temptation and sin;
But one thing assures us, we can not go wrong,
If trusting our Savior, while marching along.
Chorus.—Marching along, &c.

II.—CHIDE MILDLY THE ERRING.

36.—*Two to each Measure.* W. B. B



2.

Chide mildly the erring, jeer not at their fall,
If strength be but human, how weak are we all.
What marvel that footsteps should wander astray,
When tempests so shadow life's wearisome way.

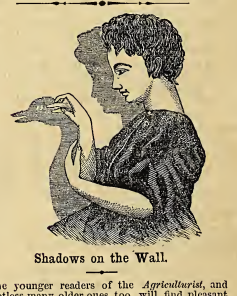
3.

Chide mildly the erring, entreat them with care,
Their natures are mortal, they need not despair.
We all have some frailty, we all are unwise, [skies.
The grace which redeems us must come from the

If our young readers do not already know one or both of the above pieces of music, we hope they will learn them speedily; we know they are good. A beautiful lesson is taught in the second piece. Let every one remember that "kind language endears."——We copy these two pieces by the express permission of Mr. Bradbury, from his Sunday School Song Book, called "GOLDEN CHAIN," and a golden chain it is, for it binds together more beautiful Songs and Hymns for children than we have ever before found together in the same space, (130 pages). The Golden Chain should be in every Sunday School, and we hope it will soon be. Our own scholars have sung it nearly through: will friend Bradbury please hurry and give us another like it? [By the 100, the price is 12 cents each, in paper covers, or if bound, 16 cents each.]

Ericsson's Iron-clad Vessel, "Monitor."

The above sketch, made for the *Agriculturist*, gives an accurate representation of this now famous floating battery, just as we have seen it daily for some time past, while going to and from home. Its wonderful deeds are already familiar to our readers, and we have room for only a brief description. It is 173 feet long, 41 feet wide, and 11 feet deep. An iron hull forms the bottom, and above this is another flat boat or frame, also partly in the water, so that only 2 to 4 feet of its sides are seen, according to the loading. The sides and top are covered with many thicknesses of rolled iron plates, each an inch thick, so that no cannon ball yet made can penetrate them. The machinery is all below water. A very thick cannon-ball-proof tower rises in the middle, 10 feet. This is 20 feet inside diameter, and in it are two largest size cannons, which are fired through port holes that are closed while loading. The tower is turned round by steam, so as to present the guns in any direction, for firing. Each ball weighs 170 lbs. The men are protected from all harm by the thick iron covering. The smoke-pipe slips down, when desired.



Shadows on the Wall.

The younger readers of the *Agriculturist*, and doubtless many older ones too, will find pleasant evening recreation in exercising their ingenuity over the two pictures here given. With a little skill, and some practice in getting the hands and fingers into the positions shown, the dark figures

GRANDPA.

can be thrown perfect and well-defined. (We have several more of these pictures ready to show you.) To make the shadows, they should fall squarely upon the wall, from a single bright light—the hands being placed nearer to the wall than to the light. If more than one wick, or more than one lamp be used, set all the wicks so that they shall be in a direct line with the hand. In this way only can a clear sharp outline be obtained. Many trials will be required to get the fingers in position—a little change of position varies the shadow greatly.

THE MAP above, is a continuation eastward of the map of the Mississippi Valley, given last month (page 89). This map shows the country, the principal towns, and railroads with their connections, of the region lying between Washington in the North-east, Charleston, S. C., in the South-east, Cincinnati in the North-west, and Atlanta, Ga., in the South-west—the last named an important railroad center. The points of most in-

Sewing Machines.

The following report was made at the late Fair held at Utica, N. Y., upon the merits of Sewing Machines. The report will be interesting to those inquiring for the best Family Sewing Machine ·

"We come now to the last articles on our list—speci-"mens of Machine Sewing. We confess our great hesita-"tion in deciding upon their merits, where all are so well "done; but feel assured that our judgment must meet "with approval when we award the First Premium to "No. 971, W. S. Taylor (Grover & Baker's Machine)-"considering the variety of articles made up of different, "materials, exhibited there. To No. 306, two machine-"made shirts, Mrs. Gallup, (Wheeler & Wilson's Ma-"chine,) we would recommend the Second Premium. "In justice to our decision, we would notice the fact that "all the specimens of work done on the Wheeler & Wil-"son Machine are upon plain, heavy fabrics, which are "not considered by the ladies so good a test of the pow-"ers of a machine designed for family use, as when "lighter materials are neatly made up by a skillful ope-"rator."

Mrs. SELDEN COLLINS, Chairman.
M s. C. S. BENNETT, M.s. GEORGE LANE, Mrs. G. O. GREENHILL, } Committee.

PREMIUM LIST,
For 1862---Vol. XXI.

Or Pay to Voluntary Agents who will attend to collecting names of new and old subscribers to the Agriculturist, and forwarding them to the Office.

☞ In selecting articles for premiums, we have aimed to get such as are *useful*. ☞ WE WISH IT DISTINCTLY UNDERSTOOD *that these premiums are offered in good faith—no cheap, trashy, imperfect, poorly made, or second-hand thing, will be sent out, but each article offered, is the best of its kind, and every one will be selected by the publisher from the very best manufactured. They will be the best sold in the market at the prices named.*

☞ Every person collecting names for premiums, should send two copies of each list of names—one of them marked "For Premiums," and also with the name of the sender.

☞ The premiums are offered for subscribers for Volume XXI (1862), *whenever received*. Canvassers will have time for completing their lists, but the premium will be paid as soon as any club is made up—if duplicate lists are sent.

Table of Premiums for 1862.

Names of Premium Articles.	Price of Premiums.	Names at $1 each.	Names at 80 cts. each
2—Clothes Wringer, No. 2	$7 50	18	37

22—Best Subsoil Plow (2-horse)	$8 00	24	48
23—Various Books—*See terms below*			

Premiums 2, 3.—Wringing Machine.

We place this first, for it is nearly new, and one of the most useful articles for every family. We had one of the first made, and have used it 1½ years with the highest satisfaction. It completely does away with the hard straining work required to wring out garments by hand. It does not twist and break the fibers of the clothes, but simply presses them between two elastic India-rubber rollers, which are moved by a crank, and whether large or small pieces, they come out dryer than when wrung by hand. The saving to garments would soon pay the cost of the implement, to say nothing of the saving of woman's labor. The machine is set upon the side of any tub; the garments drop out into a basket. A child can quickly wring out a tub full of clothes—No. **2**, costing $7.50, is just the thing for common family use.

Premium No. 4—Sewing Machine.

90 Subscribers at $1 each, (or **130** at 80 cents each,) will entitle the person sending them to *Wheeler & Wilson's* best **$45 Sewing Machine**, (including **Hemmer**), new from the factory, and of the very best make. There is no better family machine than this made, as we have proved by nearly *four* years' use in our own family.

Premium No. 8—Melodeon.

125 Subscribers at $1 each, (or **237** at 80 cents each,) will entitle the person getting up the club to one of *Geo. A. Prince & Co.'s* **$75 Melodeons** (5 octaves). These Melodeons are of very superior tone and finish. The size, prices, etc., of these instruments can be learned particularly, by sending a stamp to Geo. A. Prince & Co., Buffalo, N. Y., for an illustrated descriptive catalogue.

Premium No. 11—New Cyclopedia.

96 Subscribers at $1 each, (or **140** at 80 cents each,) will entitle the person getting up the club to a set of *Appleton's* **New American Cyclopedia**, now in course of publication, consisting of *sixteen large volumes* of 770 pages each. This is a magnificent work, forming a whole library embracing every topic of human knowledge. Fourteen volumes are now ready, and the remaining two will be furnished as fast as issued.

Premium No. 12—Best Dictionary.

18 Subscribers at $1 each, (or **40** at 80 cts. each,) will entitle the person getting up the club to a copy of the *large Pictorial Unabridged Edition of* **Worcester's Dictionary**, (Price $7 50.) This now stands confessedly the most valuable Standard Dictionary published. It weighs nearly **10** lbs.; is **12** inches long, **10** inches wide, nearly **4** inches thick, and contains **1854 pages** of 3 columns each, giving the spelling and pronunciation, with full explanations, of every word in the English Language, and as a source of general information on all subjects, stands next to the Cyclopedia.

Premiums Nos. 13 to 17—Back Volumes.

These premiums (13 to 17,) will enable any one to secure the previous excellent volumes of the *American Agriculturist*, as far back as Volume XVI. We have stereotype plates and can print any number desired of the English Volumes 16, 17, 18, 19, and 20, and of the German Volumes 18, 19, and 20. These will be clean, new numbers, each volume by itself, with index complete, and forwarded *post-paid*.

Premium No. 23—Good Books.

Here is an opportunity to get a good library at little expense. Any person getting up a club of **16** or more names, may choose any desired Books from the list advertised on page 91, *to the amount of 12½ cents for each name sent at 80 cents*, (or 33⅛ cents for each name sent at $1); the books will be *delivered to the recipient free of all expense for postage.*

☞ For descriptions of other premiums see Jan. No., page 28.

We have but little space left here, but that little will suffice to report all that is needed this month, aside from the accompanying tables, which give, in condensed form, the receipts, sales, exports, prices, etc. March is always a dull month in the Breadstuffs Market. The surplus stocks have so run down that there is not enough to keep up an active speculation. Heavy dealers are on their oars, resting and getting ready for the heavy business expected on the opening of Spring navigation. Exporters and foreign buyers are in the same condition. The exciting events of the war have absorbed much attention; and the uncertainty as to the tax bills, and the general financial arrangements of the Government, have checked speculation. The few who have been compelled to sell to meet their obligations, have not found active buyers, and, as a consequence, prices have temporarily eased off a little, but very gradually—the greatest change in price of Flour during any day for a month has not exceeded 5 cents on a barrel. On the whole, the state of the market is satisfactory, and a few weeks hence, or as soon as navigation opens, we shall look for much activity in the market again. The present stock of Wheat and Flour on hand is very moderate. Corn is in pretty full supply, and 4 to 6 cents lower than a month ago, in this market. ....Cotton fell rapidly for a time, but has recovered again recently. The present prospect is, that we shall soon have supplies from opened Southern ports, with a decline in prices.... Provisions have been purchased freely, both for home use and for shipment, at irregular prices. The receipts of Hog products continue on an extensive scale, the partial opening of the markets at the Southwest having occasioned no material diversion of supplies from this market thus far....Hay and Rice have been in rather more demand, but the tendency of prices has been downward... Hemp and Hops have been lightly dealt in ... Tobacco has been in active request, partly on speculation, in view of the probable enactment of an excise law, and prices have favored sellers....Wool has been dull and heavy in private trade, the principal feature of the month's business having been the auction sale, at Providence, March 12. The attendance of dealers from New-York, Philadelphia, Boston and Hartford, and of manufacturers, was large. The prices realized, however, were 2½@5 ℘ cent. lower than the average of sales in the market—ranging from 44c. ℘ lb., for No. 4 to XX Ohio, and from 40c. to 45½c. for common to extra New-York State. The decline is mainly due to the prospect of a speedy termination of the war, and a cessation of the demand for army clothing.

N. Y. Live Stock Markets.—THE CATTLE MARKETS have been well supplied, the weekly average being 3,809. At the market, to-day, (March 19) the best cattle brought 9c.@9¼c. ℘ lb, estimated dressed weight; second quality 7¼c.@8¼c.; poor 6c.@7c.; average of all sales, 7½c.@7¾c.; and all sold out.

Veal Calves.—Receipts for the past 4 weeks number 1,781, or 445 per week. They now sell readily at 4½c.@5c. ℘ lb live weight for poor, and 5½c.@6c. for good calves. "Kittens" or "bobs" (3 to 6 days old calves) sell at $1.00@$1.50 each.

Sheep and Lambs.—Receipts have only averaged 5,603 sheep per week during the past month. The market is now brisk at an advance of 1c. ℘ lb. Fat prime sheep sell at prices equivalent to 5¾c.@6c. ℘ lb. live weight, and fair stock 5½c. A few small Spring lambs, the first of the season, brought to-day, $4½@$5 each, or 20c.@25c. ℘ lb. for the meat.

Live Hogs.—Receipts are less, the arrivals being only 13,941 per week for a month past. Good fat hogs are in demand, at advanced rates, while poor light stock can scarcely be sold. Prime heavy corn-fed hogs sell at 4c.@4½c. and light ones, with those fed at distilleries, but 3½c.@3¾c.

Advertisements.

Advertisements to be sure of insertion must be received at latest by the 15th of the preceding month.
TERMS—(invariably cash before insertion):
FOR THE ENGLISH EDITION ONLY.
Fifty cents per line of *space* for each insertion.
One whole column (145 lines), or more, $60 per column.

at
VERY CHEAP RATES,
For the Lawn and for Hedges.
PARSONS & CO., Flushing, L. I.
The "Allen" and "Red Prolific" Raspberries.
I will sell (bundled, by Express, or otherwise, as directed) a few thousand of these *perfectly hardy* (without winter protection), highly-flavored varieties, at $12 per thousand; $8 for five hundred; or $3 a hundred plants. They should be cultivated entirely in rows 6 feet apart, three feet apart in each row, for the best bearing; or more or less, as the plants of either variety may be had—the *particular* proportion of either not being material. I still find these the best varieties of red raspberry I can propagate. Address money inclosed with order L. F. ALLEN, Black Rock, N. Y.
Large Standard Pear Trees.
For sale by B. C. WICKHAM, Tioga, Tioga Co., Penn.
A large and splendid assortment of large standard Pear Trees. Also Apple and Plum Trees, &c., &c. Ornamental Trees, Shrubbery, &c., &c. All for sale at low prices at his Nursery. Formerly Wickham & Bloodgood.
NEW CANAAN NURSERIES.
STEPHEN HOYT & SONS offer for sale, at low prices, a large stock of Fruit and Ornamental Trees. Also Vines and Small Fruits of all desirable varieties.
N. B. Apple and Peach Trees, a large stock.
New-Canaan, Conn., Feb. 1862.
FRUIT
and
ORNAMENTAL TREES
at
LOW PRICES.
PARSONS & CO.,
offer a fine stock of Fruit Trees at low rates.

Pears	35 to 50 cts.	Cherries	35 cts
Plums	33 cts.	Apples	25 cts.
Peaches	20 cts.	Versailles Currant	20 cts.

These prices are for large and handsome Trees; those of smaller size can be furnished lower. All the other kinds of Fruit, Grape Vines, &c., &c., at corresponding rates.
To those buying in wholesale quantities a large discount will be made.
EVERGREENS
and other
Ornamental Trees and Shrubs
in great variety, and finely formed and well-rooted at low prices.
For Catalogues, address at
FLUSHING, L. I.
FISHKILL LANDING NURSERIES.
D. BRINCKERHOFF & CO.,
FISHKILL LANDING, DUTCHESS CO., N. Y.,
OFFER A LARGE STOCK
OF THE MOST APPROVED VARIETIES OF
FRUIT TREES, &c.
FOR THE SPRING OF 1862.
Also **30,000** well-grown Native GRAPE VINES, of the new and highly prized sorts, about 10,000 of which are Delaware and Diana.
25,000 Currants, of all the new and reliable old sorts.
ROSES, of Hybrid Perpetual, Bourbon, Tea, Noisette, Moss, and Climbing. Experience has shown us that inoculated roses are of little value; we therefore grow them only on their own roots.
Stove, Greenhouse, and Bedding Plants,
of recent introduction, as well as the fine old sorts, in large quantities, and at low prices.
FLOWERING and CLIMBING SHRUBS, a fine stock.
50,000 Deciduous Ornamental Trees, suitable for LAWNS, AVENUES, and CEMETERIES.
75,000 Evergreen Trees, of all the most approved hardy sorts.
☞ Having been over twenty years engaged in the nursery business, our experience enables us to take up and pack Trees and Plants so that they will reach purchasers in good order.
Our prices are low, and Trees, &c., of superior quality. Catalogues sent to all applicants.
No. 1.—Descriptive of Fruits and Shrubs.
No. 2.—Descriptive of Stove, Bedding, and Greenhouse Plants.
TREES AT LOW PRICES.
For Spring of 1862.
ELLWANGER & BARRY
RESPECTFULLY invite the attention of the public to their present immense stock, covering upward of FIVE HUNDRED ACRES OF LAND, and embracing everything desirable in both
Fruit and Ornamental Departments,
Grown in the very best manner and offered either at wholesale or retail, at greatly reduced prices.
Parties who contemplate planting should avail themselves of this opportunity, the like of which may not occur soon again.
Descriptive and Wholesale Catalogues forwarded gratis on receipt of a stamp for each, and all information as to prices, &c., promptly given on application.
MOUNT HOPE NURSERIES,
ROCHESTER, N. Y.
TREES, TREES AND GRAPE VINES.
A large stock embracing Standard and Dwarf Trees of all the choicest Fruits for the Orchard and Garden, fine, healthy, well-grown trees.
Grape Vines comprise all the new and rare sorts. Beautiful Ornamental Trees and Greenhouse Plants. Orchardists and all those who wish to beautify their grounds, should embrace this opportunity, and buy cheap by the dozen, 100, or 1000, all warranted true to name. (Seedlings and Stocks for Nurserymen.) Catalogues furnished on application.
W. T. & E. SMITH, Geneva Nurseries, Geneva, N. Y.

MARBLEHEAD CABBAGE
And Other Seeds by Mail, Post Paid.

STONE MASON CABBAGE, the standard Cabbage in Boston Market. It is the most reliable for setting large, hard heads, and for sweetness and tenderness of all the Cruciferal varieties. It is a most excellent cabbage for winter use. I am daily receiving letters from persons in all the Loyal States and the Canadas, fully endorsing all the excellent qualities I have claimed for it. Packages containing one ounce of seed of my own raising, with directions for cultivation, 65 cents; one pound $2.65. Early Wimingstadt (French seed) 25 cents per ounce, this is an excellent sort for light soils and a general cultivation. Green Globe Savoy, seed of my own raising, 25 cts. per oz. Hubbard Squash, purest stock, 25 cts., extra pure Marrow, 10 cts. per package, $1 per lb. Early Paris Cauliflower, best early variety, 25 cents; Early Frame Cucumber, Newman's Improved, 15 cents; New White Spine, 10 cts.; Purple Prayer, warranted true and fresh, 10 cts.; Scotch Thumb or Strawberry Pea, grows but 8 inches high and bears with 12 pods; Darling's Early Pea, very best, of the early sweet varieties, 10 cents; Burr's Mammoth Sweet, best of all the large varieties, 10 cts.; Stowell's Evergreen Corn, excels all in keeping long in green state, 10 cents; Imperial Cabbage, 6 cts.; Imperial Cabbage, 6 cts.; Mountain Sweet Watermelon, new and excellent, 10 cents; Christmas Muskmelon, early and superior, 8 cents; Coles' Crystal White Celery, 10 cts.; Henry Fearon's Yellow Globe Danvers Onion Seed, 10 cts.; Early Scarlet Radish, 6 cts. All of the above will be sold by the ounce or pound. Catalogues of every variety of Garden and Flower Seed, with prices, forwarded gratis. Part of my seed is of my own growing, the remainder from reliable sources. JAMES J. H. GREGORY,
Marblehead, Mass.

SEEDS—SEEDS—SEEDS.

VEGETABLE, GRASS AND FLOWER SEEDS,
Embracing everything desirable, in both vegetable and flower seed departments.

For sale in quantities to suit purchasers, at the market rates. Descriptive price catalogues furnished gratis, and all information as to prices, for large or small collections, promptly given on application.

Also, a large assortment of C. S. Garden Tools and Horticultural Books.

Improved Varieties of Corn

Having experimented for many years with all the improved varieties, I have selected from 25 kinds the following as being entirely reliable:

IMPROVED KING PHILIP.—This variety I introduced in 1859. It has been extensively disseminated, producing in this State 120 bushels per acre, and 150 bushels to the acre, and in Mass. 150 bushels of ears to the acre, ripening in 100 days. Price 75 c. per peck, $2 per bush.

PROLIFIC GOLDEN DROP, a beautiful 8-rowed yellow variety, producing two ears and long ears, and holding the largest yellow corn in cultivation. $1 per peck, $3 per bushel.

MAMMOTH WHITE SUGAR.—One of the largest eating varieties, ears very long, two and three to the stalk, wonderfully productive, ripens early. $1 per peck, $3 per bushel. This is a very valuable variety. Address

WM. S. CARPENTER, 468 Pearl-st., New-York.

THE NEW LETTUCE!

TRUE BOSTON CURLED LETTUCE.—I introduce this new variety from reliable growers, in this country and in Europe, and at wholesale and retail.

EXCELSIOR

BURR STONE FARM MILL.

AND

ANTI-FRICTION

HORSE POWERS.

These Mills and Powers took TEN FIRST PREMIUMS at WESTERN STATE FAIRS last year, and are justly considered superior to all others.

These Mills can be run by any HORSE, WATER, OR STEAM POWER. For grinding all kinds of GRAIN, SPICES, COFFEE, PLASTER, BONES, SOAP STONE, &c., they have no equal.

Large Mills are made for milling Meal once requiring but ONE HALF THE POWER to do the work of large flat stone mills. The HORSE POWERS have many advantages over those of other manufactures.

See *American Agriculturist* for 1861, pages 237 and 268, also page 31, in this volume.

Agents wanted in every county. State, County, and Shop Rights for sale. Send stamp for Illustrated Circulars to

BROWN'S BRONCHIAL TROCHES

A Slight Cold, Cough, Hoarseness, or Sore Throat, which might be checked with a simple remedy, if neglected, often terminates seriously. Few are aware of the importance of stopping a Cough or Slight Cold in its first stage; that which in the beginning would yield to a mild remedy, if not attended to, soon attacks the lungs.

Brown's Bronchial Troches were first introduced eleven years ago. It has been proved that they are the best article before the public for Coughs, Colds, Bronchitis, Asthma, Catarrh, the Hacking Cough in Consumptian, and numerous affections of the Throat, giving immediate relief.

Public Speakers and Singers,

will find them effectual for clearing and strengthening the voice.

Sold by all Druggists and Dealers in Medicine, at 25 cents per box.

CAUTION.

The Lodi Manufacturing Co. wish it distinctly understood, that *other brands* of Poudrette than theirs are in market, put up in barrels to resemble theirs, and that the following, viz:

Staten Island Poudrette Co.,
Griffing Brother & Co. Poudrette,
Xcelsior Poudrette,

all emanate from the same place on the Staten Island salt meadows.

That although the barrels are a good imitation, the material inside is *totally different*, being coarse and black, full of rye, neaty fibers, and free from rubbish, while the Lodi Manufacturing Co.'s Poudrette *contains no peat*, is the *exact color of dessicated night soil*, a grayish brown, and contains the usual amount of foreign matter, coal ashes, gravel, etc., in minute particles, with which the night soil of great cities is always mixed, and which it would be too expensive or impossible to separate. A little stacked lime is a-ways mixed with twice its bulk of Poudrette, slightly moistened and rubbed through, will soon convince the most ocpse nasal organs, as to which is a genuine article, by the ammoniacal smell arising therefrom. Our only orders are for the pure article. The Lodi Manufacturing Co., established 22 years.

THE LODI MANUFACTURING CO.,
60 Courtlandt-st., New-York.

Fine bone dust, *warranted pure*, also for sale.

PROVIDENCE COMPANY'S CONCENTRATED BONE FERTILIZER.

This is the best Fertilizer, at the price, ever offered to the farmer.

It is composed of pure bone, ground fine, with other materials added to give it immediate effect.

It powerfully stimulates the plant from the moment the seed germinates until harvest.

It will not only fill the farmer's crib, but will enrich the soil. Try it.

It is packed in good flour barrels, and delivered to vessel or railroad, in New-York City, free of charge for carriage, at the following prices:

For one barrel, $2; two, $3 50; three, $5; four, $5 50; five, $8; six, $9 50; seven and over, $1 50 per barrel.

Two barrels will manure one acre of corn in the hill.

Send your orders, inclosing the cash, by mail, to

GRIFFING, BROTHER & CO.,
No. 60 Courtlandt-st., New-York,
Who are Sole Agents for the United States.

GENUINE

SUPER-PHOSPHATE OF LIME,

Manufactured from **Raw Bones**, dissolved in *Sulphuric Acid*, with a few important additions, at $40 *per ton*, by

A. LISTER & BROTHER, Tarrytown, N. Y.

(For results of the past season see *American Agriculturist*, for August, 1861, page 282.)

We guarantee every tun of our manufacture to be of uniform quality, and invite trials or chemical analysis.

We also manufacture from RAW, (OR UNBURNED), BONES, the fine, medium, and coarse ground **Bone Manure**, for lasting as well as immediate effect upon all kinds of farm crops. The coarse ground particles are valuable for *Fruit Trees* and *Grape Vines*, which require a constant and lasting source of nourishment.

For sale in large and small quantities by

A. LISTER & BROTHER, Tarrytown, N. Y.,
and their agent, F. LANGMAN, 129 Water-st., New-York.

COE'S SUPERPHOSPHATE OF LIME.—
Office 189 & 191 Water-st., New-York.

For testimonials of this valuable fertilizer address it. H. ALLEN & CO., as above.

Also for sale, R. L. Allen's MANIPULATED GUANO, No. 1 PERUVIAN GUANO, POUDRETTE, PLASTER OF PARIS, and all other fertilizers.

RHODES' SUPER-PHOSPHATE.
THE STANDARD MANURE.

We have establshed an office at No. 97 Pearl-st., New-York, for the sale of Rhodes' Standard Manure, and will be represented by Mr. H. E. MORRIS, to whom dealers will please apply. B. M. RHODES & CO.,
Office 32 South-st., Baltimore, and
97 Pearl-st., near Hanover Square, New-York.

100,000 Barrels
OF THE
LODI MANUFACTURING COMPANY'S
POUDRETTE,
FOR SALE BY
JAMES T. FOSTER,
No. 66 Cortlandt-st., New-York.

The large facilities which they enjoy by exclusive contract for all the night soil of the City of New-York, and large capital invested in their extensive works, enable them to manufacture an article which is superior to any other fertilizer in market, taking *cost and yield* into consideration. It will be sold at the usual price of $1 50 per barrel for seven barrels or over, delivered free in New-York City.

Please take notice that the office and sale of this Company's Poudrette is changed from Messrs. Griffing, Brother & Co., No. 60 Cortlandt-st., to No. 66 CORTLANDT-ST.

Other brands of what purports to be Poudrette are in market, put up in barrels to resemble this. Beware of frauds—buy that only which has the brand of the Lodi Manufacturing Co. Any other article is comparatively worthless.

We call the attention to the following experiences of practical farmers, in different sections of the country:

NORTH PEMBROKE, Mass., Oct. 7, 1861.

James R. Dey, Esq., President of the Lodi Manufacturing Co.:

Dear Sir—The early autumnal frosts for several years past have seriously injured our corn crops, and rendered it necessary for farmers in this section to seek some fertilizer that their crops an early start, in order to bring them to maturity in season to avoid that calamity. Having experimented with Guano, Superphospate of Lime, etc., with indifferent success, in the spring of 1860 I purchased four barrels of the Lodi Manufacturing Co's Poudrette, which I applied principally on my corn crop, with the most satisfactory results. This was the first Poudrette ever introduced into this vicinity. Last Spring I purchased from your branch office in Boston about thirty barrels, the most of which I sold to my neighbors, who had witnessed the effect of my last year's trial, which, so far as has been heard from, has given universal satisfaction. To further test the efficacy of your Poudrette, this season I ploughed under two acres of light, sandy soil, which had laid in grass about six years, (the last crop very light.) Upon this I planted with corn and potatoes, applying about four and a half barrels of Poudrette. In other manure I applied a handful of ashes to each hill at the first hoeing and from present appearances I shall have a better crop than on a field of like soil where we applied twenty-five loads of manure to the acre. Its effects on garden vegetables are equally apparent. I am, very respectfully, yours,

HORACE COLLAMORE.

MERRILL, Me., Oct. 11, 1861.

Lodi Manufacturing Co.:

Sirs—I bought of your agents, Cross & Newell, two barrels of your Poudrette, and in using the first, I got sick of it and sold the other barrel. But the one that I used I tried the principal part on potatoes. I used about half a pint to the hill, and the yield was equal to those planted on manure at the rate of twenty loads to the acre. My neighbor, who bought the other barrel, says if he had bought five barrels more, he would have saved the price of twenty barrels.

Yours, &c., V. B. PAUL.

WALDO, Me., Oct. 12, 1861.

To the Lodi Manufacturing Co.:

Gentlemen—Last Spring I bought of Cross and Newell one barrel of your Poudrette and experimented, but with very little faith in its utility. I put it on six rows of corn in different parts of the field, after running with a barrel of manure, in the usual way—at the second time hoeing. Where I put the Poudrette the corn was twice as large as the rest of the field, and the ears on it one-third heavier, and has ripened about eight days earlier. I think it the very thing we want for raising corn on this country, and shall use it more extensively another year. Yours, &c.,

WELLINGTON SHOREY.

SMYRNA, Del., Oct. 1, 1861.

Gentlemen—I had heard of the Poudrette manufactured by the Lodi Manufacturing Co., and bought it, would try a small quantity on a lot of land intended for corn, and as I could not get it nearer than Philadelphia, I went and bought of the agent twenty barrels, and applied two barrels to the acre, dropping the corn and a handful of Poudrette in each hill. I left out a part of two rows, and put no Poudrette, to ascertain if there was any value in it, and noticed those two rows during the season, and the Poudrette produced a heavy crop, the corn was decidedly the best, and I have no hesitation in saying it is a good manure for corn. I am certain I made from one-third to one-half more by using it.

Yours, respectfully, JOHN G. BLACK.

CHESTER, Pa., Sept. 15, 1861.

To the Lodi Manufacturing Co.:

Gentlemen—I purchased this season of Messrs. Baker & Co., eleven barrels of Poudrette and one bag of Phnlin, which I put on my corn. I marked the place where I put the Phnlin, which, without being scattered about, but now the corn where the Poudrette was on is much the best. Last year I used Allen & Wendle's new Fertilizer, which did no good at all, as the corn done better without the manure. I think the Poudrette made by your Company the cheapest manure in use. Yours, &c.,

A. B. PERKINS.

The Company's pamphlet, containing directions for its use, with other valuable information and the experience of over one hundred farmers, will be sent free to any one applying for the same. Address,

JAMES T. FOSTER,
Care of Lodi Manufacturing Company,
66 Cortlandt-st., N. Y

American Agriculturist in German.

THE AMERICAN AGRICULTURIST is published in both the English and German Languages. Both Editions are of the same size, and contain, as nearly as possible, the same Articles and Illustrations. The German Edition is furnished at the same rates as the English, singly or in clubs. A club may be part English, and part German.

Premiums for Northern Grown Cotton.

One Hundred Dollars are offered for the best five specimens of cotton grown above latitudes 38° and 40°, this year. See particulars in February *Agriculturist*, page 64.

Subscriptions Still Date January 1st.

Unless otherwise specially ordered, all new subscriptions received before June 20, will be entered from January 1st, and the back Numbers be forwarded.

EXTRA PREMIUMS,

Only from April 1 to May 10, 1862.

(And at no other time.)

Our general Premiums for Vol. 21 are continued as usual, (see list on page 122). To meet the wishes of very many who have recently written us on the subject, we make a special offer, which applies *only* to subscribers *hereafter received* up to May 10th, 1862. (These subscribers are not to be included in the general premium list.)

STRAWBERRY PLANTS Sent Free by Mail.

The best improved Strawberry for general use, of which plants can now be obtained in quantity, we believe to be the **Triomphe de Gand** variety. We have arranged to have a limited supply of excellent plants, which we will put up in the best possible manner, and forward them by mail, *post-paid*, on the conditions named below. (In the warm weather of last August and September we forwarded many thousands of plants in this way, and after diligent inquiry, we hear of barely two parcels which did not go safely. The rest all did finely, we believe.)

CONDITIONS

I. To any person forwarding, after April 1st, and before May 10th, ONE subscriber to the *American Agriculturist*, at $1 a-year, (*to begin Jan. 1st, 1862,*) we will present (if desired) **Ten Plants of the Triomphe de Gand Strawberry,** forwarded free. These plants set in good soil early this Spring, will multiply greatly the present season, and furnish plants enough to start a large plot in August, for fruiting next year.

II. To any person forwarding, after April 1, and before May 10, TWO subscribers to the *American Agriculturist*, at $1 each, (for the year 1862,) we will send (if desired) **Twenty-five Plants of the Triomphe de Gand Strawberry,** to be forwarded free as above.

III. To any person forwarding, after April 1st, and before May 10th, THREE OR MORE subscribers for the present year, (from Jan. 1,) at $1 each, we will present, **for each name, Fifteen Plants of the Triomphe de Gand Strawberry,** to be forwarded free as above.—N. B. When three or more names are sent together, the recipient may order, if desired, one-fourth of the plants to be the BARTLETT STRAWBERRY, a new and very promising variety.

N.B.—1st. Three days before sending out the above plants, a printed slip or circular will be mailed to each person entitled to receive them, notifying him of the day on which the plants will be mailed, so that they can be looked for on their arrival. The printed slip will also contain directions for treatment of plants, soil, culture, etc.

2d. If plants are to be called for at the office, please give at least two days' notice, that we may bring them in from the country at the specified time.

3d. Special to Canadian Subscribers.—In a few cases, Canadian Postmasters have charged *letter postage* (3 cents an ounce,) on the arrival of plants and seeds which we had prepaid here. There seems to be no regularity, and we can not yet get any definite decision from the General Secretary at Toronto. We therefore advise Canadian subscribers who desire to avail themselves of the above premium offers, to arrange to receive the plants at some United States Post-office on the lines, or if this be impracticable, to receive them by Express, making the club of names large enough to render this an object. When thus sent *by express* to Canada, at expense of recipient, we will double the number of plants.

Bound Volumes—Binding—Covers.

We have complete sets of Vols. 15, 17, 18, 19, and 20, both unbound, and bound separately in neat covers with gilt lettered backs.

PRICES AT THE OFFICE.

Volumes 16, 17, 18, 19, and 20, *unbound*.....$1.00 each.
Volumes 16, 17, 18, 19, and 20, *bound*.....$1.50 each.

PRICES WHEN SENT POST-PAID BY MAIL.
(*They can not go unpaid.*)

Volumes 16, 17, 18, 19, or 20, *unbound*.....$1.12 each.
Volumes 16, 17, 18, 19, or 20, *bound*.....$2.00 each.

BINDING.—Sets of numbers brought to the office will be bound up neatly (in our regular style of binding the *Agriculturist*) for 50 cents a volume.

PREPARED COVERS.—Covers for binding, neatly made, with title, etc., gilt upon the back, ready for the insertion of the sheets by any bookbinder, can be furnished for Vols.12, to 20 inclusive, at 25 cents per cover. *Covers can not go by mail.*

An American Exhibition OF Pumpkins, Squashes, and Ornamental Gourds.

Our English neighbors are just waking up to the value of the Cucurbitaceous Family, (pumpkins, squashes gourds, etc.). The Royal Horticultural Society of England, for the first time in its history, has arranged for a "Great Gourd Exhibition" next October, and invites all the world to competition. As Americans, we would like to compete with Great Britain, and all Europe, in raising Pumpkins and Squashes, and we at first thought to ask our readers to send all their specimens to the *Agriculturist* office, to be forwarded to London, at our own expense. But the London Exhibition is appointed too early (Oct. 8,) to allow our specimens to fully mature, and be forwarded. Let us then have an AMERICAN EXHIBITION, and see what can be done *here*. The results can be compared, and we shall then know whether we would have been successful or not, could they have been sent to London. The results will be the same, and equally beneficial in stimulating improvement.

There being no Royal Society here, we will undertake it single handed, and offer prizes fully equal to those of the London Society. (Two individual offers of £5 are made by Dr. Lindley, and Mr. Wilson Saunders). If any gentleman will do the same here, we will be happy to announce it next month. Our own proposal is as follows:

There will be a Public Exhibition of **Pumpkins, Squashes, and Ornamental Gourds,** at the office of the *American Agriculturist*, 41 Park Row, New York City, opening on Wednesday, Nov. 5th, 1862, at which the following prizes will be paid by the Publisher, upon the award of competent Committees.

CASH PREMIUMS.

I.	For the *Heaviest* Pumpkin or Squash..	$20.00
II.	For the 2nd do. do. ..	10.00
III.	For the 3d do. do. ..	5.00
IV.	For the Best do. do. for cooking..	10.00
V.	For the 2nd Best do. do. ..	5.00
VI.	For the largest yield on a single Vine.*.	10.00
VII.	For the 2nd do. do. *.	5.00
VIII.	For the largest and finest collection of Pumpkin, Ornamental Gourds.*.....	10.00
IX.	For the 2nd do. do. *.	5.00

* All to be grown by one person and to be accompanied by an affirmed statement from the grower, and two disinterested persons who assist in gathering and weighing

Note 1.—The specimens receiving the Prizes will remain on Public Exhibition at the pleasure of the Publisher who offers the prizes. The other specimens will be subject to the order of the exhibitors, or be sold at Auction or otherwise disposed of, for their benefit.

Note 2.—All Exhibitors must notify us of their intention by Oct. 20th, and deliver specimens for competition on or before Nov. 3d. All specimens must be delivered free of charge. ORANGE JUDD, *Publisher*.

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, PLANTS, and FLOWERS for the LAWN or PARK; care of DOMESTIC ANIMALS, &c., &c., and to HOUSEHOLD LABORS. It has also an interesting and instructive department for CHILDREN and YOUTH.

A full CALENDAR OF OPERATIONS every month.

THREE, to FOUR HUNDRED, or more, illustrative ENGRAVINGS appear in each volume.

Over TWELVE HUNDRED PLAIN, PRACTICAL, instructive articles and useful items, are given every year.

The Editors and Contributors are all PRACTICAL WORKING MEN.

The teachings of the AGRICULTURIST *are confined to no State or Territory, but are adapted to the wants of all sections of the country—it is, as its name indicates, for the whole* AMERICAN CONTINENT.

TERMS.—INVARIABLY IN ADVANCE,
(For either the English or German Edition.)

One copy, one year.....$1 00
Six copies, one year.....5 00
Ten or more copies one year....80 cents each.

☞ Add to the above rates: Postage to Canada, 6 cents; to England and France, 24 cents; to Germany, 36 cents.

Postage anywhere in the United States and Territories must be paid by the subscriber, and is *only six cents a year*, if paid in advance at the office where received.

All business and other communications should be addressed to the Editor and Proprietor,

ORANGE JUDD, 41 Park-Row, New York City.

FROM THE STEAM PRESSES OF JOHN A. GRAY.

AMERICAN AGRICULTURIST,

FOR THE

Farm, Garden, and Household.

"AGRICULTURE IS THE MOST HEALTHFUL, MOST USEFUL, AND MOST NOBLE EMPLOYMENT OF MAN."—WASHINGTON.

ORANGE JUDD, A.M., EDITOR AND PROPRIETOR.
Office, 41 Park Row, "Times Buildings."

ESTABLISHED IN 1842.
Published both in English and German.

$1.00 PER ANNUM, IN ADVANCE.
SINGLE NUMBER, 10 CENTS.
For Contents, Terms, etc., see page 160.

VOLUME XXI—No. 5. NEW-YORK, MAY, 1862. NEW SERIES—No. 184.

Entered according to act of Congress in the year 1862, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York.

☞ Other Journals are invited to copy desirable articles freely, if each article be credited to *American Agriculturist.*

May

"The most unfurnished with the means of life,
And they that never pass their brick wall bounds,
To range the fields, and treat their lungs with air,
Yet feel the burning instinct."—

The passion for rural life comes as near to being universal, as any sentiment that rules the human heart. It is universal, notwithstanding the very large population congregated in cities, and that never expect to live elsewhere. The poor and thriftless live there not as a matter of choice, but of necessity. They find themselves in the city without any volition of their own, and they have not force of character enough to get out into the country, where land is cheap, and thus strike for independence. If they labor at all, they are accustomed to labor for others, to spend as fast as they earn, and to suffer when they can find no employment. They have no faculty to set themselves at work, and have never tried to make money earn money by trade, or mechanical employments. With all their longings for fresh air, and sunlight, they expect to live and die in the miserable tenements poverty compels them to occupy. The laboring thriving class in the cities, mechanics, clerks, and small tradesmen, have visions of rural bliss, which they expect to realize, but they are so far in the future that they have not yet taken definite form. They do not earn enough to admit of their living in the country while they do business in the city, or their business does not admit of such an arrangement. Country life is an expensive luxury, in which they hope they shall one day be able to indulge. Multitudes who have attained this felicity, do not know exactly how to afford it. The rent is cheaper, but the rides they find cost quite as much as in the city, and the markets are as dear. Vegetables and fruits do not come so early, and they are generally sold higher than in the city. Country life is very delightful, but it uses up a salary of $2,000 just as effectually as life in the city. The children enjoy it, are fat and happy, and are learning a multitude of clever things, that they could not know in the city; the wife is pleased, the society is good, and the schools are as a general thing, quite as good as in the city; but it all costs too much—it can't be afforded.

"How to make rural life pay?" that is the question with all classes who ever expect to enjoy a home of their own in the country. There can be no doubt that multitudes, perhaps a majority who go into the country spend from a quarter to a third more than they need to, because they do not avail themselves of the advantages of the country. The theory of living is different in the county. Here a man produces every thing he can economically. In the city he buys everything, paying for it with his skill, labor, or capital, sold in the market. The citizen has no time to study the art of "making one hand wash the other." In the country, this is the great secret of economical living. You go into the country to have room, a house, and a few acres of land, delightful rides over the country with wife and children, to entertain your cousins and family friends with strawberries and cream, fresh laid eggs, and broiled chickens, in their season. Now if you buy all these nice things at your rural home, you will find the bills quite as large as in the city, and possibly larger. It is the easiest thing in the world for a family to run up a bill of three or four hundred dollars at the village stable, and then feel that they have not had half riding enough; two hundred dollars at the butcher's, feeling that they have had to stint themselves in poultry; fifty dollars with the milk man, with but half a supply of milk, and no cream at all; four hundred dollars at the grocer's, with eggs only once a week, and lean pickings at dessert.

Now we shall manage these things very much more economically, if we adapt ourselves to the conditions of rural life. You have two objects in view in a rural home, economy, and the better education of your children, meaning by that, what they get outside of the schools. It is worth a good deal to a family of children, to have them familiar with all the details of country life, the care of domestic animals, the management of a flower and vegetable garden, familiar with the trees of the wood, and plants of the field. Things move in a circle in such a home, and every link in the chain must be complete to make the rural home a paying concern. If you have land it must be worked to make it bear crops. To do this economically, you must have labor and manure. To have these in the most economical form, you must keep a man, and domestic animals. You have to pay out money for your help, and for your provender, but you get for it cheap rides, and all you want, cheap eggs, poultry, milk, cream, cheap fruits and vegetables, and the rural schooling for the children, which is a matter of prime importance.

Your man will cost you not far from $120 a year and his board, the keeping of the family horse, with the interest of money invested, and the wear and tear of vehicles, harnesses, etc., about $100, and the cow from $40 to $75, according to size, skill in management, and other considerations. You will want two pigs and thirty hens to complete the circle. These gather up the fragments, and turn the last particle of refuse matter to profitable account.

You want Patrick the year round, to attend to the horse and the cow, and with a little management, he need not have an idle hour. In the Summer he takes care of the garden, teaches the boys to hoe and spade, to harness the horse, and ride him, to hunt hen's nests, and feed the chickens. In the Winter, when the horse is not in demand for rides, he is busy drawing muck and manure. In such an establishment 40 or 50 cords of manure may be made, which will keep the land in a high state of productiveness. Patrick pays his way in garden products, a full supply for the family, with a small surplus for the village market, and a few hundred bushels of beets and carrots for the cow and horse. The horse pays his way in drives, and in aiding Patrick in his winter work. The cow pays her way in milk and cream, and if a very good one, in butter for three months in the year. The skim-milk goes to the pigs, and to mixing meal for the hens. The market value of her products will be from $50 to $100, according to the excellence of the animal, amount of feed, etc. The hens will pay their way in eggs and poultry. We have kept accounts for several years, and found the profits to average about $1 for each fowl kept through the year. The expense of keeping where all the food is purchased, is also about $1 each. The pigs are economical as coworkers with Patrick, in manufacturing fertilizers, and for furnishing about 600 pounds of pork and hams, of much better quality than you can buy in the market. There is nothing like the pork packed in your own cellar, for the weekly dish of baked beans, and that other dish known in its glory only in the country, succotash. There are no hams like those cured after your wife's recipe, as good a year old as when first cured, but always failing to keep a year, for the best of all reasons—they are eaten.

With us, rural life pays, and we can readily see that others can make it pay very much better than we do. But the art of living in the country, and indeed of living at all has always to be learned, and it is quite easy to see that the learning may be somewhat expensive. We offer these brief hints for those who are taking their first lessons this Spring, assuring them that with economy it will pay, and warning them not to anticipate too much the first season.

Calendar of Operations for May, 1862.

[A glance over notes like the following will generally call to mind some piece of work that would otherwise be forgotten or neglected. The remarks are more especially adapted to places between 39° to 43°; but will be equally applicable farther North and South, by allowing for latitude.]

Farm.

How to economise time and labor and to accomplish most during the present month, is the farmer's study. Many a farmer undertakes to do so much work himself that he breaks down under the pressure, while he should have spent part of his time in planning to make work go smoothly, to have no hurrying, no work to be done over again, and to have no body on the farm who interrupts the work of others, or is out of the way when wanted, or shirking his share of the tough jobs, and looking out for easy ones. The farmers of our country should remember that all prosperity, especially in this country, is dependent upon the products of the soil, and so use the whole fertility of the soil and the manure-heap to the best advantage, and with confidence in Him who giveth rain in due season, and ordereth the seed time and the harvest.

Beans will do pretty well on poor soils, but a great deal better on good. They run to tops if the ground has too much fresh manure, and are an excellent crop for clearing land of weeds. They are always marketable, valuable for home use, and for feeding to sheep. Plant white tonia varieties in drills 2½ feet apart. See article on p. 142.

Bees—A moderate apiary can be easily attended to with little expense and trouble, and with great profit. See directions given under "Apiary," on a subsequent page.

Birds—Spare them all; put up bird boxes. More than one or two compartments are undesirable. Kill cats that kill birds; allow no guns fired on or near the premises.

Bones—Collect from far and near with jealous care; pound them up or put them in with the horse manure.

Broom Corn—Plant late in the month, on good corn land in hills, 3 feet each way, or in drills 4 feet apart, thinning subsequently to 6 inches apart in the rows.

Buildings—Paint before hot weather comes on, if at all this season. Remove all litter from unused stalls and the bottom of bays, before it becomes a harbor for rats and mice and insects, which soon take possession when the premises are left undisturbed.

Calves—For weaning see Calendar for April; feed sweet hay after they begin to graze; castrate at 4 weeks old.

Carrots may still be sown; the earlier the better.

Cattle—Continue to fodder until there is abundance of grass. Keeping them a week out of the pasture now will be of great service to it before the end of the Summer. They will relish a little hay at night even after turned to pasture. Keep up the flow of milk by feeding cows with wet bran, shorts, and roots if any remain, until the pastures are in full growth. Feed grain to working cattle according to the severity of their labors. Potatoes or other roots once or twice a week will keep them in good, healthy working order.

Cranberries—This is the best month to set cranberries on wet land. Obtain good healthy plants from the swamp and plant them on skinned and burnt swamp land or on light moist upland, and keep clean.

Cellars—When the cellars are empty, clean them out in every nook and corner, and whitewash throughout, and stop rat holes with cement and broken glass.

Clover—Where winter grain is thin and back ward from any cause, clover and grass seed will catch if sown early.

Corn—Prepare the soil in *dry* weather early in the month, never work the ground when it is wet. The old rule of the Indians was, to plant when oak leaves are as large as a mouse's ear. If heavy greensward be broken up like Spring, do not cross-plow, and be careful not to disturb the sods in harrowing and marking out the ground. The fermenting sods will afford warmth and nutriment. Examine carefully and reject all imperfect seed. If wet and dried off with lime, smutting is prevented. See p. 142.

Dairy—The labors of the dairy are commonly more burdensome this month than any other. Plenty of rich milk, with good help, makes the work light.

Draining—Mark spots that need draining, and be prepared to put in the "crockery" or stones next Fall in good earnest; and improve drouths, at any season, to drain low swampy land.

Flax and Hemp—Flax culture promises to become more remunerative in future, from recent improvements in preparing the fiber. Sow this and Hemp early.

Fences—Keep all in repair, particularly boundary and road fences, and around pasture lots where young cattle are confined. Good fences make quiet cattle. If they once become unruly, no ordinary fence will restrain them.

Grain Fields—A top dressing of plaster, nitrate of soda, or guano will often prove beneficial on both Winter and Spring grain. Guano, lime, or wood ashes, sown liberally before the seed is covered, will benefit heavy soils. Keep all stock from grain fields, and pull out weeds as soon as plainly visible before the grain is too large.

Grass Seed—May be still sown upon grain fields not already seeded, and on poor meadows. Use plenty of seed.

Hedge Rows thrive and spread by being let alone. Tear them out by the roots, not only along the fences, but by the roadsides to prevent further encroachment. If time can not be taken for this, turn a flock of sheep upon them to eat off the young sprouts as they appear, which will destroy some, and keep all in check.

Horses—Need, to keep them in good condition during Spring work, generous feed and thorough grooming. Collars, cart, and harness saddles should fit perfectly, and these are much better hard than soft. Soft pads induce sweating, and galls, if the skin be broken. A piece of hard leather, cut to fit the neck and shoulders under the collar, is a great relief to a tender skinned horse. Sponge the heads, shoulders and legs night and morning.

Horse-hoes—In all cases where hand hoeing can be dispensed with, and the work done by horse-power, do so. The tillage is commonly much more thorough, because oftener repeated and done at so much less expense.

Lime—Always apply it on land after plowing deeper than before, and upon the surface, for it works down. Keep a supply on hand for composting with weeds, sods, etc., 30 bushels to the acre, after plowing in other manure, is an excellent preparation for corn.

Lucerne—This clover rarely succeeds north of latitude 41°. It requires deep soil with open subsoil, on which it thrives year after year without renewal, and furnishes valuable feed, particularly for soiling, as it can be cut several times in a season. Use 10 to 12 quarts per acre, and sow early, best in drills 2 feet apart, and keep clean.

Mangel Wurtzel—A most valuable root for stock. Sow first to middle of May, on good strong deeply tilled land, 4 inches apart in rows 2 feet apart, bury the seed an inch deep, one seed in a place, if you can trust the seed; where seed fails, plant by transplanting.

Manures—Corn is a gross feeder, and should be well supplied with all that can be profitably used. The effects of heavy manuring on hoed crops will be visible years after, in the oats, winter grain, and grass which follow. Buy manure only as a last resort, after all available supplies on the farm are exhausted. Bone dust, and Peruvian guano, where a good article can be obtained, cotton-seed oil-cake, castor pomace, and beef scraps, (the first two ready for immediate application, the rest requiring composting a few days with soil,) may often be bought and used to advantage. For grass or grain fields the Peruvian guano, nitrate of soda, or sulphate of ammonia if obtainable, applied in solution, are best. See article on Concentrated Manures, page 138.

Mowings—Allow no grazing in Spring, top-dress with fine compost before the grass has advanced much, or apply guano, ashes, or plaster, early this month if needed. Keep the wash channels open from the road, and arrange them to distribute the water over a wide space. See p. 138.

Oats—A crop may sometimes be got if sowed late, but they do not fill well. If the ground is in perfect order and you can put on nothing else conveniently, sow oats about the first of this month; but if rains come on, devote the land to some other crop. If your object is to seed down to grass, sow any time this month, and cut the oats for hay.

Onions—See Calendar of Operations for April.

Peas for feeding out may be sown early in the month. A low growing variety put in with oats, will be partially supported by the grain, and both will yield a good crop in a favorable season.

Parsnips—Afford a valuable feed for milch stock; should be sowed about the middle of May rather shallow, in drills 2 feet apart. Parsneps make lighter drafts upon the soil than any other root crop, except onions, but delight in a deeply worked light rich soil.

Plowing—Lay out long lands, and avoid curved furrows. Whenever practicable follow with the subsoil plow. There is no other good preparation for deepening the soil by subsequent plowings, and it is a great preventive of injury from drouth.

Potatoes—Plant early in drills 3 feet apart, use no heating manure, but well rotted compost, ashes, etc.

Poultry—If confined, keep up their lay ing by liberal feed of grain, boiled potatoes, and frequently some chopped meat, and grass or other green food. Allow them to leave their yard an hour or two before sundown, when they will not do much injury by scratching in the garden, etc. Hens with chicks should be confined in portable coops and chickens allowed to roam in the garden and fruit yard until they begin to scratch badly; they will destroy many insects. Feed young poultry with cracked corn instead of meal, increasing the size as they grow older, until they can manage whole corn. Milk curds are very wholesome food for them. Turkeys ought not to be set before this month, and when hatched the young birds must be housed in a dry shed, and not allowed to get wet by dew or rain for several days.

Provisions—Pork in barrels in the cellar, hams in the smoke-house, and other provisions, need looking after occasionally. Add salt to the brine if it needs it and see that it covers the meat. Hams sewed in thin muslin bags and whitewashed, will rarely be troubled by the fly. Keep them dry and cool.

Pumpkins—Cheese pumpkins are probably the best variety for cooking. Keep them separate from other vines of the same family. See article on page 142.

Root Crops—Carrots, see Calendar for April,—Ruta bagas, sow middle of June.—Parsneps, Mangels, and Sugar beets, see elsewhere in Calendar.

Sheep—Shear early without washing unless the sacri fice on the wool will be too great. Shear scabby sheep and dip in a strong decoction of tobacco, scrubbing them with a brush; watch the first symptoms of foot rot, and if it shows itself at all, after driving the sheep through shal low water or wet grass, to wash their feet, drive them all through a narrow passage in which a long trough is placed, holding a concentrated solution of blue vitriol, quite warm, in which they must take several steps. See article on page 137.

Soiling—Winter rye is earliest ready for the scythe, then oats and peas sown early and repeatedly, later clo ver, and for the same purpose successive crops of corn sowed broad cast or in drills. The evergreen sweet corn is one of the best varieties for this purpose, though the common western or southern do well. Sorghum, Egyptian millet and common millet, and Hungarian grass, are all good summer soiling crops.

Sugar—The uniformly good returns received from a cultivation of this plant and manufacturing syrup and sugar when judiciously conducted, particularly at the West, stimulate its extended culture. Procure seed only from reliable sources—inferior sorts have caused much disappointment. Prepare the ground, plant and cultivate as for corn. See page 139.

Sugar Beets—Cultivate like mangel wurtzel in all respects, to which it is superior as food for milch cows.

Swine—Give to sows with litters plenty of nourishing food. The best pork is obtained from pigs kept fat and growing rapidly from first to last. If bran, shorts, or meal be given, mix with sour milk, or water, and allow it to ferment before offered for feeding out. Connected, a steaming apparatus should be attached to every establishment where many swine or other animals are fattened.

Tobacco—Weed plants in the seed bed, and water with liquid manure, dung-heap leaching diluted, sheep-dung water, or guano water. Follow directions in articles on Tobacco in this and other numbers.

Tools, machines, harness, etc. To keep all in perfect order is employment for the many rainy days common in this month. Examine well and procure the best mowing machine before the grass is suffering for want of cutting. A farmer should be acquainted with the merits of as many of the new implements as possible. Oil harnesses after they have been wet, and before they dry.

Orchard and Nursery.

Fruit trees should have been transplanted in this lati tude, by the middle of April. At the north, late growing sorts may still be set out, and if neglected until now, they may be planted even now, in this latitude. Care will be necessary not to rub off the growing buds, and the roots must not be exposed to drying winds. Mulch the ground around late planted trees to guard against a drouth before the roots have taken hold of the soil. Cut back a good portion of the previous season's growth to infuse vigor in the remaining branches. A lagging tree either established or newly planted, will often push into a new and healthy growth by a severe heading back. See page 145.

Seedling stocks should all be planted out at the earliest moment, if still heeled in. Successful planting frequent ly depends very much upon the time of setting out. The soil is usually always good after the winter rains and snows, and if planted at that time the stocks or trees become established before the drouth which usually occurs the last of May, or first of June sets in.

May is emphatically the evergreen planting month, and the nurserymen are busy in taking up and sending away pines, spruces, hemlocks, firs, arbor vitæ, etc. So well do they understand the difficulty of successfully trans planting native evergreens from the forest, or open pas ture even, with their coarse fiberless roots, that most of our common trees are now raised from seed in the nur sery, or at least taken from the pasture while quite small and set in the nursery rows to form a mass of fibrous roots. They are frequently transplanted two or three times before they are finally sold, or in lieu of this they are dug about and the tap root cut, to induce side roots

and fibers. Even those grown with the most care, require some attention in their removal than deciduous trees. The roots should not be exposed to the sun or drying winds, and with some kinds, such as the broad leafed rhododendron and laurel, it is safest to remove the tree or shrub with a ball of earth attached. The same may be said of trees taken from the woods or pastures. Wet the ground thoroughly, dig carefully, and having secured all the roots possible, with the earth attached, slip a gunny bag or other stout cloth under the mass and tie the corners up about the trunk. Move it carefully and set at once, filling in a little peaty soil about the roots, if possible. If a favorite pasture or road-side tree is wanted in the lawn, commence upon it this Spring, digging about and severing some of the larger roots, but not too many of them. Fill in with fine soil and leave the tree to form new fibers during the season. The tree may be moved the succeeding Spring, to ensure against the liability of failure, the remainder of the principal roots may be cut the following Spring, and left for another season's growth.

In exposed situations and especially in prairie regions, it is very advisable to shield the newly planted orchard from the prevailing winds. Plant a belt of evergreen and deciduous trees upon the north, east and west sides of the site intended for an orchard. Set the deciduous trees on the outside as a partial protection to the evergreens. In clearing up a forest, a belt of trees two or three rods in width, left to protect the orchard, will be very serviceable.

In the orchard there is little to do, if the directions given last month were fully carried out. A few grafts may still be put in the apple trees, provided the cions were cut in April or before, and have been well kept. Remove all brush, loose stones, and other rubbish from the orchard and if the ground has been a long time in sod turn it over lightly, previously adding manure. The only pruning now admissable is to remove decayed branches, and small shoots, thinning and heading back with the pruning knife.

Insects will begin to show themselves this month. Commence a vigorous assault upon them at once, before they have time to increase in numbers. A little work in the apple orchard will destroy many caterpillars' nests. Wash trunks of small trees with strong soap suds or potash water to remove scale. Give cherry and pear trees a sprinkling of oil soap solution, towards the close of the month, to kill slugs. Examine trunks of trees for borers.

Seedlings budded last season should be examined, and all shoots starting out about the bud rubbed off. Cut the stock to within two inches of the bud, unless already done.

Weeds will soon make their appearance in the nursery if not kept in check. The plow or horse-hoe will do most of the work, but the hand-hoe will also be needed to remove weeds in the rows. Use a short wifflетree, and pad the ends to prevent barking the trees.

Kitchen and Fruit Garden.

During last month most of the preparatory work of draining, manuring, and trenching, should have been done, many seeds sown, and some already beginning now to appear above ground. It is easy by a little extra care in protecting tender plants, as beans, melons, cucumbers, etc., to secure their ripening two or three weeks earlier than otherwise. Gauze covered frames will protect against quite severe frosts. Hand glasses are convenient and more effectual, but liable to scorch the plants. A pane of glass on four bricks answers a good purpose.—When rain has fallen after seeds have been sown, and the surface has dried rapidly, it will facilitate the appearance of the tender shoots, to gently loosen the crust above them, with care not to injure the growing plants. A loose surface is most favorable to growth under all circumstances, but the ground should be often stirred and the crust broken to admit air, warmth, and moisture to the soil below. Plan so as to have a succession of crops on the same soil—lettuce between the carrot and parsnep rows and among the hills of melons; cabbages among early potatoes, to stand after potatoes are dug, turnips after the peas and early beans, endives or celery to follow early crops in the same way.

Asparagus—Cut every shoot as it rises to sufficient hight for the table, by which means the season will be much prolonged. Be careful in cutting not to injure the young shoots below the surface.

Beans—Plant bush varieties early. The Princess, China and Valentine are earliest; Union, Rob Roy, Marrowfat, Large White Kidney, and Refugee, later. The Lima stands first among pole beans, but is late. The Dutch Caseknife, and Red Cranberry are earlier. Set poles before planting the hills, which should be raised an inch or two above the surrounding surface, and plant after the middle of the month. The Lima's are tenderest. Set the flat beans, eyes down, and shallow.

Beets for early use should now be up. They may still be sown. Sow for Summer, Early Bassano; for Winter use, Long Blood, or Blood Turnip, sowing in deep, mellow soil, in shallow drills, eighteen inches apart.

Borecole and Broccoli—Sow for late crops at any time after the middle of the month, and transplant ready grown plants to the open ground from the hot-beds.

Cabbage and Cauliflower—Sow for late use, and transplant from the hot-bed into rich mellow ground. Examine about the roots for the cut worm. Hoe former plantings frequently, in the morning when the dew is on.

Carrots may still be sown, though it should have been done earlier. See April Calendar.

Celery—Sow for main crop as directed last month.

Cistern—For large gardens, a capacious cistern to be filled from the roofs of adjacent buildings, is a great convenience. During drouth, a hose from a hydropult or garden engine may be introduced, and a thorough watering be given with little trouble.

Cold Frames—Remove any remaining plants as soon as there is no danger from frosts, and store the frames for another season. An occasional coat of paint and care in handling, will preserve them many years.

Corn—For family use plant sweet varieties at two or three different times during this month, and as many next, giving to each about equal space. For market plant once early in this month or in April even, and after the middle of May, make a planting once a week until the 4th of July. Darling's early sweet is a good variety, and the Evergreen sweet, a large growing late kind, but very good table corn. Some of the small eared New-England varieties are sweetest. Plant small varieties in north-and-south drills, 3½ feet apart, 3 kernels to the foot.

Cucumbers—Transplant those started in the house as directed last month. Plant seeds for a succeeding crop. Our practice is to make large hills and put in, at intervals of a few days, several rows of seed around the first planting, to attract insects which may escape other preventives. Superfluous plants are removed when the danger is over. One of the best preventives is cotton batting, a thin layer spread over the plants and pegged down.

Egg Plants—Transplant from the hot-bed into ground well enriched with warm fermenting manure, when the weather is warm and settled.

Fruit Trees—The main fruit yard should be separate from the kitchen garden, but dwarfs do well in it where their shade will fall on walks, or where it will do no harm. Dwarf pears thrive in the soil of a well tilled kitchen garden. It is not too late to do a good deal of transplanting of fruit trees, grapes, etc., if the buds have not started, and the trees are in good condition.

Hot-Beds—Remove all plants from them, paint and put away sashes and frames for another season.

Insects—Many are already on the alert. Whale oil soap, guano water, and hen-manure solutions are not only offensive to them, but give vigor to plants to resist attacks Covering with gauze frames, is almost a certain preventive.

Kohl Rabi—Sow and cultivate like cabbage; plants may be placed somewhat nearer together.

Kale—Green curled kale and other varieties may be sowed at this season, and treated like late varieties of cabbage. See April *Agriculturist*.

Lettuce—Transplant from hot-beds, and provide for a succession among hills of vines, etc. Set it in unoccupied places. Frequent watering with liquid manure and often hoeing will bring it to perfection.

Liquid Manure Tank—Every kitchen garden should be provided with some convenience for making a solution of manurial substances. It should be near a supply of water, be sunk in the ground, and tightly covered. A barrel or half hogshead in will do, but a tight box in which is a partition with holes at the bottom is better. Against the holes on one side is thrown a quantity of shavings kept in place by a few stones, then any kind of litter or manure. Upon this we may throw a few pounds of guano, or sheep, or hen manure, or sulphate of ammonia, and pouring on water it will percolate and come well strained through into the other side fit for use. It is most important that it be not applied too strong. Water at evening, not letting it touch the plants, unless they are infested with insects.

Manure—A supply for a large garden may be obtained by saving sink and chamber slops, and using the contents of the privy. Offensive substances are made inodorous by mixing with them plenty of muck, or by sprinkling liberally with sulphate of lime (plaster of Paris).

Melons—Musk, Canteloupe, Nutmeg, etc. Sow seeds as directed for cucumbers. The *seed* is worthless, and the flavor of the fruit injured, unless raised at a distance from other cucurbitous plants.

Nasturtiums—Sow where they will be shaded from the mid-day sun. They thrive best with plenty of moisture.

Okra—Sow in very rich soil, in shallow drills, 3 feet apart, and thin to a foot distant in the row.

Onions may still be sown. They do best several years on the same soil.

Peas—Sow for a succession of crops. The Champion of England variety is generally preferred for the main crop. A convenient method of supporting peas, is by means of stout cords stretched between stakes or posts at the ends of rows, supported in the middle if needed.

Peppers—Plant out from the hot-bed, eighteen inches apart, in rows two feet distant.

Potatoes—Plant at any time during the month, the earlier the better; late potatoes are of little use in the garden. The Dyckman, Ashleaf Kidney, Peach Blow, Wendell Seedling, and Dover, are excellent garden sorts. The last not early, but excellent. Hoe former plantings, and top-dress with ashes and plaster.

Pumpkins—Plant in hills eight feet apart, and at a distance from melons or squashes. Where different varieties of such vines are cultivated in the same enclosure, it is a good arrangement to surround each plot with several rows of peas, which will partially prevent their mixing.

Quinces—See article on page 145 of this number.

Radishes—Sow in vacant spaces, for a succession.

Rhubarb—Set roots or, if not supplied, sow seed. Hoe out all grass and weeds, and keep the surface loose. Pull leaves, removing only the stalks, and leaving the leaves for a mulch about the plants. Cut out the seed stalks as soon as they show themselves.

Salsafy—Sow on soil deeply worked, like carrots.

Seeds—Test before sowing largely. Set out roots or plants intended to furnish seeds for next year. Different varieties of the same species, as cabbages, turnips, etc., of various sorts, should be widely separated, to keep the seed pure. To get good squash or melon seed reserve spots in corn or potato fields far apart, for raising them.

Squashes—Treat like cucumbers and pumpkins.

Sweet Potatoes—Plant out when the weather is settled and warm, in deep, well pulverized soil, enriched with stable manure. Set plants from fifteen to eighteen inches apart in high ridges, or in hills, about three feet from center to center; set them obliquely and so that the stems of the lower leaves will be covered; they will then sprout again, if cut off by frost or worms.

Tomatoes—Transplant from the hot-bed into a well enriched sunny bed, 4 feet apart each way. A sandy soil is favorable. In setting the plants, place them a little deeper than they originally stood—they will throw out fibrous roots from the stem. Prepare a light inclined trellis to support the vines.

Turnips—Sow for Summer, hoe, weed, and thin others.

Winter Cherry (*Physalis*)—Plant out the same as tomatoes. Seed may still be sown, soaking it first.

Small Fruits.

Blackberries may be transplanted and succeed well any time before the buds swell for leafing out. Cut back well.

Cranberries—See note in Farm Calendar. They may be cultivated with good success in the garden.

Currants may be planted or moved, but at the sacrifice of the fruit if it be done after the buds have burst. Pruning to a single cane or stalk to each root, and this trained at an angle of 45°, and only very short spurs allowed to grow, is a system growing in favor.

Grape vines neglected in the proper season for pruning may be pruned as soon as the leaves appear, without danger of bleeding, and early in the month vines may be planted to good advantage, though better earlier.

Mulberry—This is suitable for an ornamental tree. Downing's everbearing is hardy and excellent.

Gooseberries—The Houghton does not mildew, and is therefore the best to plant. As soon as the leaves appear dust with sulphur.

Raspberries—Enrich the ground beneath and about them, by surface dressing. Cut out all feeble canes and winter-killed parts.

Strawberries—See notice of superior varieties offered as premiums. Set in good light, or well worked soil, water freely and frequently, giving a very little liquid manure in each watering. Bearing plants should be mulched with straw, tan-bark, lawn clippings, or coal-dust, to keep the berries out of the dirt. We prefer tan-bark.

Flower Garden and Lawn.

How apt are we all to regard as valuable and useful only, or chiefly, those things which minister to our bodily wants, or bring us some material profit. Why should the demands of the body and its comfort and enjoyment pull down the soul to its own gross level. Once supplied with food and clothing, let the mind have a free range, and the soul delight itself in beauty, and grow in the sunshine of nature, which is beautiful, often in proportion as it is of no other use.—If old beds are to be re-arranged, do it at once. In transplanting, disturb roots as little as possible. The frames, pits, houses and conservatories can be emptied in the course of the month, of all but stove plants. Most of them will do best, turned from the pots into the open border. Intersperse them among the bulbs, annuals

and late blooming perennials, where they will make an immediate show, and keep up a succession of bloom.

Amaryllis, one of the finest Autumn blooming bulbs, should be set early in a warm border.

Annuals—Sow in fine, well enriched warm soil. It is essential that a good variety of fine blooming annuals should now be put in, to keep up a show of flowers late in the season, after most of the perennials have cast their blossoms. Most of those sown in the houses to foward their growth, may now be transplanted to the open ground.

Bedding plants, as verbenas, petunias, salvias, heliotropes, Japan pinks, lantanas, pelargoniums, and others, may be readily obtained of the gardeners. The tender ones should be set out as soon as danger from frost is past. It is best to set each variety by itself, more or less.

Asters—Sow in open ground early, in various places, where they are to remain; later in the month transplant from hot-bed or frames. A few may still be started in boxes, if the ground be not ready—to transplant afterwards.

Biennials and Perennials—When it is desirable to increase the stock, remove a portion, and leave the remainder undisturbed.

Box Edging—Keep close clipped and low; reset if necessary as directed in April Calendar; renew weak or wintered-killed spots.

Bulbs—Keep well supported, and stretch a light awning over the choicest, to lengthen the period of bloom, removing at night and during cloudy weather. Set Autumn blooming varieties, as amaryllis, gladiolus, tuberose, lilies of various kinds, etc.

Carnations and Pinks may now be set out already in bloom. Tie to neat stakes. Divide old roots, and make layers to form new plants.

Cypress Vine, Morning Glory, and other annual climbers may be sown immediately and trained to strings around a central pole. Unsightly buildings, rough fences, etc., can be almost hidden beneath a mass of bloom, when covered with these climbers. Cypress vine seeds vegetate much more freely when soaked in tepid water for 12 hours before sowing.

Dahlias—Sprout them in boxes of earth, or by burying in a warm border previous to planting the last of May.

Evergreens—Delay planting until the last of the month after the trees have begun to grow, except arbor vitæ and Norway spruce. Keep the roots from the sun. Hollies, rhododendrons, and other broad leaved evergreens, do better when removed with a ball of earth attached.

Frames and Pits—Remove any remaining plants.

Flowering Shrubs—See Calendar for last month. Some are suready in bloom, or have cast their flowers; the later kinds may still be planted.

Gladiolus—Set the bulbs in a warm sunny place. Some of the newer varieties are very pretty.

Grass—Keep well trimmed and close clipped along the edges, using a line and sharp spade, or edging knife. New turfing may also be laid; keep well watered until rooted.

Gravel Walks should be kept free from weeds with the shuffle-hoe, and be well covered with clean, coarse gravel, and rolled.

Fancy Gourds—Sow early, and train upon fences, trellises, or old trees.

Hedges—Complete setting deciduous, and arbor vitæ, early, other evergreens later. Clip any not attended to last month.

Honeysuckles, Wistarias, Ivy, Ampelopsis, Bignonias, Clematis and other perennial climbers—Set at once, if neglected until now. Arrange on trellises or lattice work. Sow seeds and make layers.

Insects—It will be much easier to keep them in check if they are combated upon their first approach.

Lawns will need mowing, and should be cut frequently and evenly. A good, cheap, lawn mower is needed.

Lupins—Sow early and give plenty of room.

Mulching is beneficial to newly planted trees and shrubs. Lawn clippings are excellent.

Pruning—Prune with reference to habit and manner of blooming; the knife may be used freely at all seasons, if used with discretion. Shrubbery needs to be kept dense to look well. Evergreens should branch quite down to the ground. Their outer extremities may be cut back slightly, to make a dense growth.

Roses—Let the supply be large and varied, if space permit. The common June or garden roses must yield to remontants, teas, and bourbons. Tie up pillar and climbing sorts, layering the old wood. Turn those in pots into the open border.

Shade Trees—It is not too late to plant if they have not leafed out. Some will bear moving even then.

Trellises and Upright Frames—Set if loosened by frost, renew if decayed, before vines and climbers are put out.

Tuberoses—Plant bulbs not potted, early in very warm good soil. See description given last month.

Green and Hot-Houses.

As few plants are retained under glass as possible, all that will bear the exposure, as soon as they are sufficiently hardened by free ventilation, are removed to the open ground. There is little fear of frost after the middle of this month. Roses and bedding plants are turned out of their pots. Keep all growing plants well watered and syringed. Plant out fuchsias in partial shade.

Pelargoniums—Cut back severely, and set out the prunings in masses. Oleanders, Myrtles, Oranges and Lemons, may be sunk in their pots or tubs—examine for scale bugs.

Grapery and Orchard-House.

Give good ventilation; syringe foliage, walls, and ground, freely and often. Thin out fruit if it is too thick. Go through thoroughly pinching in shoots wherever needed. Grapes require especial attention; mingle sulphur in the water we syringed with, and dust it upon both fruit and foliage. Abstain from syringing any fruit in bloom, and let bees have access if they will.

Apiary in May.

Prepared by M. Quinby—by request.

The weather during fruit blossoms, decides whether we have early or late swarms. Should the yield of honey be plentiful, *good* stocks will be prepared to throw off swarms the last of this month. But, should a scant supply be obtained through unfavorable weather, swarming would be put off indefinitely, and even second or third rate stocks may throw out the first swarms. It sometimes happens that strong colonies having a good supply of last year's honey, and gathering but little now, will consume it this month, rearing drones. They even make preparation for swarming—rearing queens so far as to seal them up. A dearth of honey nearly always occurs between fruit and clover blossoms. The drones are sacrificed to save the colony. The bees in such cases change their plans entirely. If they get honey almost immediately, it will take several weeks before they can again get into condition to swarm—providing another brood of drones and other preliminaries just lost. Stocks that were quite feeble in March, with light stores, that could not afford to rear a drone, and that used with economy what they had, will pass such season of scarcity without any suspension of breeding, and be ready for swarming first. This explains why poor stocks will occasionally turn out better than such as were best at beginning of Spring. Should a swarm issue during such a time of scarcity, it will need feeding, particularly if there should be cold wet weather. Some of the poorest colonies can not always be trusted to supply themselves at such times, and will need feeding also.

Swarming will not be general until white clover appears. Use for swarms no hives that have been recently painted. Have every thing in readiness for the swarms as they issue. When they have clustered, there should be no delay in getting them into the hive. The time lost in preparing a hive, and having the bees wait for it, often results in *their not* waiting. *Good luck* here, consists in getting all the swarm to enter the hive, carrying to the stand, shading from the hot sun, and raising the front side just a little, without delay.

Those who begin to rear Italian queens this month, will need a full colony of that kind. It will be hardly possible to procure a queen much before the first of June. A queen just introduced to a native colony, is just as good to breed queens from, as if she was in a hive of her own bees. To begin—after the preparations already suggested—the first thing, after a colony is sufficiently strong, is to introduce the frame with small frames into the center of the hive—described in Feb. *Agriculturist*—taking out an outside one, and moving the others outward to make room. The queen will soon deposit eggs in some of the small combs, when they are ready. Raise out the frame carefully—using smoke to keep the bees quiet—slip out one, put another in its place, and return to the hive. Fasten on the top of this with screws, or pieces of wire bent around a thin strip of wood projecting half an inch beyond the corner, by which to suspend it. Three such combs are needed, but only the middle one need have eggs. Have ready before hand about a quart of bees—in warm weather a less number will do—to introduce to this box, without a queen of course. Open a hole in the top of the box in which they are confined, and set the one with the comb properly adjusted over it in such a way that no bees will escape. Feed a little and keep shut up for two or three days. When bees can be procured at another yard a mile away, the shutting up is not important if set a little distance from any others. They usually construct three or four cells, and the first queen that matures will destroy all the others. To prevent this, about the tenth day take out the comb and cut off without injury all the queen cells but one; there may be given to other little colonies for maturing. The queen matures in twelve days after they are shut up, ordinarily, and will commence laying in eight more, when she may be introduced. It is found to be very hazardous to introduce an Italian queen to a colony of natives, sooner than a week after they have been deprived of their own. Let the stock be strong enough to divide, when half of the combs and bees may be put into an empty hive adding frames to fill each. Set two feet apart, each a foot from the old stand; the one that is like to get the most bees may be put further off. In a day or two, the half without a queen, will begin royal cells; and of course the other hive is the place to look for the old queen, which may be destroyed. In eight days look over the combs again minutely, and cut off *every queen cell*—success depends upon it. The queen now to be introduced, may be enclosed in a tumbler, with two or three bees as attendants, and secured with wire cloth. Remove the honey board—the board over the frames—and invert the tumbler directly on the frames where the bees are thickest; set over the cover two boxes, to keep them warm. In the course of twelve hours, the bees and queen will become sufficiently acquainted through the wire cloth to be allowed together. Take off the tumbler carefully without disturbing the bees, set on the cover again, when she will quietly go down into the hive, and commence depositing eggs at once. This is the whole process. The Italian seem to work more readily in this way than the natives. I think it quite probable that this mode of propagating queens artificially, will yet be generally adopted. The introduction of a mature fertile queen to a colony two weeks sooner than when they swarm naturally, is an advantage sufficient to pay for extra trouble. The time gained in breeding, is equivalent to a swarm.

Grape-Growers' Maxims.

BY A. S. FULLER.

1—Prepare ground in the Fall, plant in Spring.

2—Give the vine plenty of manure, old and well decomposed; for fresh manure excites growth, but does not mature it.

3—Luxuriant growth does not always ensure fruit.

4—Dig deep, but plant shallow.

5—Young vines produce beautiful fruit, but old vines produce the richest.

6—Prune in the Autumn to promote growth; but in the Spring to ensure fruitfulness.

7—Plant your vines before you put up trellises.

8—Vines, like soldiers, should have *good arms.*

9—Prune spurs to one well developed bud, for the nearer the old wood the higher flavored the fruit.

10—Those who prune long must soon climb.

11—Vine *leaves* love the sun; the *fruit*, the shade.

12—Every leaf has a bud at its base, and either a bunch of fruit or a tendril opposite to it.

13—A tendril is an abortive fruit bunch—a bunch of fruit is productive tendril.

14—A bunch of grapes without a healthy leaf opposite, is like a ship at sea without a rudder—it can't come to *port.*

15—Laterals* are like politicians; if not often checked they are the worst of thieves.

16—Good grapes are like gold; no one has enough.

17—The earliest grape will keep the longest; for that which is fully matured is easily preserved.

18—Grape eaters are long livers.

19—Hybrids are not always high-bred.

20—He who buys the *new* and *untried* varieties should remember that the seller's maxim is *Caveat emptor.*—Let the buyer look out for himself.

* Laterals are shoots which start from either side of the main bud, at the axil of every leaf; if they grow unchecked they destroy its vigor; if entirely removed, the bud itself shoots prematurely.

Training Tomatoes.—A correspondent writes to the *American Agriculturist:* It is poor policy to set them in rich soil; let it be of just moderate fertility. Give them the warmest part of the garden; set small pieces of bush around them until they have grown eighteen inches or so high, then drive in notched stakes along side of the rows, say about two feet high, and on these notches lay poles—bean poles will answer—on each side of the rows; as soon as the vines are high enough lay them on these poles, this will expose them to sun and air and keep the fruit clean. The tomato may be trained, also, like a grape vine, on a low trellis or sunny wall; the yield of fruit is enormous, and on a warm wall the first frost will do no real injury.

Containing a great variety of Items, including many good Hints and Suggestions which we give in small type and condensed form for want of space elsewhere.

The General Premiums Still Good. For want of room we omit the list of General Premiums. They can be found on pages 122 of last month, page 90 (March), and in full on page 27, (January). We invite all our friends to continue their kind efforts to promote the circulation of this journal.

Crop Reports—Blanks.—On or before April 23d, Blank Forms were mailed to all whose names and addresses had been received up to that date, and we are continuing to send these blanks to other names that come in from day to day. These blanks should be received by the first of May. If there are any failures or losses by mail, please inform us promptly. The sheets contain separate blank forms for five montnly reports, beginning with May 10, on which day the first report should be *mailed*. In order to be inserted in the June *Agriculturist*. We shall be glad to have many more names of those who will assist in this public enterprise, especially from localities in the great corn and grain growing regions of the middle and western States, not yet represented. We are thankful in behalf of the country for the interest already manifested. In many places, Farmers' Societies, and Clubs, have taken hold of the matter with spirit, appointing competent reporters to receive the blanks, and promising constant co-operation on the part of the officers and members. In several instances the President or Secretary of a County Society has been appointed, and he in turn has chosen assistant reporters in each town in the county—a capital idea. We have devised a system of numbers, which will convey a great amount of information in regard to the breadth and condition of the crops, in a very small space. Our next paper will show the method and its results.

Interesting War Maps, are spare room on pages 153, 156 and 157. We could hardly spare room for them, but in these times we cheerfully respond to the general wish of our readers, so fully expressed in letters.

Missing Seeds, etc.—The call for Seeds has been so unexpectedly and unprecedentedly great, that many kinds, though laid in largely, have run out entirely, and could not be replaced. The run upon particular kinds has been very great. Take No. 183, for example. We had all the seed from a quarter acre of our own production, and at first sent out good sized parcels; then the demand increased, and we lessened the amount of seed to each; then we bought all the extra seed we could, and yet run short. The same may be said of Nos. 168, 202, 207, 208, etc. Some parcels have doubtless been lost by mail—we hope not many, for they have cost us trouble and expense enough to have them all go safely. We have certainly spared no pains to do all we promised and more, and to satisfy every subscriber. See "Defective Seed Envelopes" in another column.

The Strawberry Premiums offered last month are still good, and will be up to May 10th. We limit the time, as it will not be absolutely safe to send plants by mail at a later date. We are now sending out many thousands of plants each week, but shall doubtless have enough for all who apply for the premiums during the time specified. Our plants are very fine; they were *grown* by A. S. Fuller, in his nursery grounds on Myrtle Avenue, Brooklyn, L. I., and he is so sure of their superior quality that he is quite willing to join us in guaranteeing their excellence.

A Strawberry Show is announced on page 160, to which attention is invited. The occasion will doubtless be one of much interest, and useful information will be brought out. All who have good strawberries to show, and those who like to see them, are invited.

See the good Advertisements, on pages 155, 158 and 159. They were necessarily divided by the maps, which could only be printed on one side of the sheet.

Central Park Conservatory.—We understand that the Central Park Commissioners have made an agreement with Parsons & Co., of Flushing, by which they secure to the City a constant exhibition of the finest exotic plants in a large show house, or conservatory, to be erected on the Park near Fifth Avenue, and in return for their expenditure for this purpose, and their annual payment of a specified sum to the Park, have granted them a license to sell cut flowers and plants in pots. The Conservatory will probably cost fifteen thousand dollars, and is to be built two stories high. The upper story will be on a level with and adjoining Fifth Avenue, and will be built on brick arches and iron beams. Its size will be 160 feet long, and 40 feet wide. This will be the principal show-room, and will be filled with the most beautiful flowering and foliage plants, growing in the soil, while the finest exotic vines will cover the roof and columns. The rooms below and on a level with the Park, will consist of a Camellia-house, 40 by 60 feet, a Fernery; 40 by 60 feet; and two large rooms 48 by 60 feet each, to be used as sales-rooms. Smaller rooms in the rear will be occupied for making bouquets, for offices, and for a horticultural library to which all visitors will have access. It is designed to have exhibitions of single classes of plants, as Geraniums, Fuchsias, etc., of which large quantities are to be grown at Flushing, or by other florists who incline to send good plants there for sale on commission. We look upon this enterprise with great interest because it will make our citizens familiar with the finest plants, and educate their taste. Florists generally will be benefitted also, as the improved taste will greatly increase the demand for flowers and plants. The Central Park Commissioners have doubtless done a good thing for the public.

Planting Strawberries.—To several inquirers. The best time to make new beds for fruiting, is in August and September, using the well rooted new plants from the runners of this year. If set early in autumn they will bear well next season. Plants set out in the Spring get well established, and if on good, rich soil, send out abundant runners which take root at the joints, producing new shoots. If to be made the most of, put them at least two, or better three, feet apart; turn the runners so that they will not interfere; and when needed, fasten the joints loosely to the ground with a very small forked branch. Nearly or quite every joint so pinned down will take a root. A bit of earth, or a pebble will answer to hold the joints down.

Adirondac Grape—Correction.—In speaking of this grape, page 117, April *Agriculturist*, we said it was exhibited at Montreal, Canada, in *October*. The introducer, Mr. John W. Bailey, writes us that he showed it at Montreal on the 18th of September, *fully ripe*. He claims that it ripens four to five weeks earlier than the Isabella, and ten days before the Hartford Prolific. We know nothing as to its *quality*.

Royal Hort. Society (Eng.).—The great shows take place this year at "The Garden," South Kensington, London, on May 21st, June 11th, and July 2d. In October there is to be a show of fruits, roots, gourds and squashes, vegetables, and cereal grains, which is open to all countries. We hope that efficient means will be taken to make a show of American products in London. It may open an important market.

How Much Rain in a Year.—An interesting table prepared for the *Agriculturist* will be found on page 154. It will be seen that the fall of water, in the form of rain and melted snow, has for seven years past, averaged 50¾ inches per year, or sufficient to cover the whole surface with water to a depth of over 4 feet. The least fall was in 1856, not quite 43 inches. The greatest fall was in 1858-9, being over 56 inches (56.16). The fall for the year ending March 1st, 1863, was nearly 56 inches (55.97). The mean fall for seven years by seasons was: Winter months 12.29 inches; Spring 13.16 inches; Summer, 12.87 inches; and Autumn, 12.18 inches—showing no great difference in the mean fall for the different seasons. The largest fall in any month, in June, 1857, being over 18 inches, (18.09)—an inch for every five days.

The "Cheap Watch" Humbug.—Messrs. "Bostwick, Tiffany & Co."—Just as the April *Agriculturist* went to press, we began to receive letters of inquiry and remittances of money, from $8 to $20 each, to be invested in watches offered wonderfully cheap by "Bostwick, Tiffany & Co., New York." On referring to the advertisement in the *Weekly Tribune*, we found that, under the above name, some party, (perhaps the "Sands of Life" man, or the Rev. Wilson, or one of that ilk,) had assumed, in part, the name of the old well-known dealers, Tiffany & Co., and with much pretence of hard times, offered watches at "ruinously low prices." The advertisement itself was sufficient evidence to us that it was a swindle. We first wrote a letter, in a friend's name, stating that we had $20 sent us to invest in a watch, and asked Messrs. "Bostwick, Tiffany & Co.," (so-called) *where* we should bring the money. The reply was, that all the watches were sold out, and their establishment was about being moved to Philadelphia, where any communication would reach them. We next called personally upon Mayor Opdyke, who promptly seconded our efforts to stop the swindle. He dispatched Capt. Silvey, of the Metropolitan Police, ordering him to arrest whoever should call at the Post Office for letters for "Bostwick, Tiffany & Co." The next day we received a note from the Mayor, stating that Capt. S. had arrested the swindler and found upon him $400. There being none of the actually swindled persons here to enter formal complaint, the villain could not be held, and is now doubtless engaged in some other scheme under another name. We returned all the money chancing to be entrusted to our care. As a single mail brought him $400, probably he collected thousands of dollars, and would have got many thousands more had we not stepped in to stop his career. MORAL—When anybody offers to sell you two dollars worth of silver or gold for one dollar of the same metal, set him down as a humbug, a thief in disguise.

Instruction about Fruits and their Management.—The best general work on this subject is doubtless "Downing's Fruits and Fruit Trees of America." It names all the best fruits and gives a description of each—figuring many of them—and gives ample directions for their culture. It contains 560 octavo pages and costs $1.75, sent post-paid by mail, or otherwise.

"Hints to Horse Keepers."—("J. W." New Haven, Conn.) This book is what its simple title purports, and a great deal more than one would suppose. Henry William Herbert (Frank Forrester), we may almost say, made a life study of horses, and this book is a compendium of much valuable experience, and most enlightened views. It is fully illustrated, contains 425 pages, and is emphatically a good *hand-book* for horse-men. (Price $1.25. The same if sent by mail post-paid.

Book on Gardening for Ladies and Beginners.—"Julia," Cook Co., Ill. We know of no book better adapted to a novice, than Mrs. Loudon's "Ladies' Companion in the Flower Garden," edited by A. J. Downing. It does not contain *all* the new plants and flowers, for it is several years old, but is full of correct and practical information. It is an octavo of 430 pages, the descriptive part double columned, and well illustrated. (Price sent by mail, $1.50.)

A Pleasant Fertilizer for Garden Plants.—Many persons, particularly ladies, dislike to use the ordinary fertilizers from the barn or poultry yard, on flowers and other house-plants. "One who knows" sends the following for the *Agriculturist*, which is good not only to stimulate house-plants, but for out-door plants of almost every kind. Dissolve ½ to ¾ ounce of sulphate of ammonia, (obtained cheaply at the druggists) in one gallon of water. Apply it only once a week, and then only to growing plants. It may be used with great benefit on beds of strawberries, on peas, on dwarf pears, grape vines, dahlias, and for all kinds of pot-plants. This mixture increases the size of the foliage of plants, and gives a dark, shining green color. The flowers also are improved in proportion. And, not least important, this fertilizer will do no harm.

Six Good Dwarf Pears.—A good judge, in Central New-York, recommends: Duchesse d'Angoulemc, Louise Bonne de Jersey, Beurre d'Amanlis, Urbaniste, Beurre Diel, and Vicar of Winkfield.

Defective Seed Envelopes.—As stated in the last *Agriculturist*, page 101, a large number of applications for seeds have been made, in which the subscribers failed to follow the directions given in connection with the list. This has been done accidentally, no doubt—perhaps carelessly in some cases—but that will not prevent their alotting the blame to us. Indeed, we have had a few severe letters from those whose envelopes are on hand, but not defective to be used. We have paid many dollars of postage on letters having the old stamps or none at all, while many subscribers have put on three cent stamps where one cent would have answered. We have on hand many of these defective envelopes. Here are a few which are without the P. O., or without the list of seeds desired—other envelopes lack any address, though they have the seed lists: *Vermont:* W. S. Grow. *Rhode Island:* A. Aldrich. *Connecticut:* W. A. Hyde. *Massachusetts:* G. H. Dyer, H. R. Storer, C. Gardiner, S. Green. *New York:* T. Pierson, L. M. Chambers, S. Fordham, J. A. Pain, F. W. Smith, L. Weirich, J. Tongue, G. Jarrold, A. E. Dayo, A. Matson, O. Reed, A. M. Hitchcock, S. F. Roberts. *New Jersey:* R. T. Abbott, C. W. Moore. *Pennsylvania:* J. Richardson, G. Grier, L. C. Troutman, W. House, D. Datweiler, N. Haughy, A. J. Watson, H. Broman. *Illinois:* P. Conner, H. Baars, J. W. Coventry, V. K. Dayo, C. G. J. Hughsone. *Wisconsin:* H. B. Lee, E. Kendley. *Indiana:* T. B. Graham, R. R. Kofel, J. P. Clough, H. Matthews, I. Henley. *Ohio:* S. Phelps, A. Branden, D. Farnas, W. Negley, P. S. Bull, N. H. Townsend. *Iowa:* S. O. Crandall, J. M. Chapman, S. S. Eagan. *Michigan:* I. J. Carver, D. C. Higbee, L. E. Ferguson. *Kansas;* D. R. Brees, S. Ogden, D. R. Overly, M. A. Bunch. *Minnesota:* J. V. Dugan. *Delaware:* W. C. Mitchell. *Maryland:* D. A. Price. No State or Post Office given: A. Weaver, J. B. Brooks, R. F. Rollins, B. F. Bullis, S. S. Rector. Dr. Gilmore. Many others are otherwise defective. If the above will send in a list of ten to fifteen numbers to select from, with full address, we may yet be able to supply four or five parcels each.

Vitality of Seeds.—Nearly all seeds retain their vitality more than one year; some are good for twenty. But the old story of the mummy-wheat is beginning to be discredited. It depends very much on the way seeds are gathered and preserved. They should be collected just at the point of full ripeness, not after, then laid away to dry. At leisure, they may be rubbed out, sifted, and put away in paper bags, labelling them at the time. They should be kept in a dry place and at an even temperature. Before planting, throw your seeds into a dish of water; those which float are generally worthless—not always. A surer way is to try to sprout them in boxes of earth before planting. Those whose tested portions do not germinate may be thrown away.

Treatment of the Amaryllis.—"Reader," Hampden, Me. The Amaryllis requires a period of rest after blooming, or after the new growth which follows blooming. Set the pots in a dry portion of the house, and give very little water for 2 or 3 months.

Flowers and Ruta-Bagas.—"Jane." You mistake, if you think a man can not be interested in the useful and the beautiful at the same time. We hope your lover will have an eye to both. Look at the example of sturdy Wm. Cobbett, the author of the "American Gardener," who first introduced the ruta-baga turnip into this country, and cultivated it with great zeal and success. This plain man wrote thus: "For my part, as a thing to keep, not to sell, as a thing the possession of which is to give me pleasure, I hesitate not a moment to prefer a fine carnation plant to a gold watch set with diamonds." Please, Jane, don't sneer at plain men, again.

Propagating the Daphne Mazereon.—T. Farrar, Kenosha Co., Wis. This is a pretty flowering shrub, blooming very early in Spring, before the leaves appear, and on this account it is better to transplant it in the Fall. Increase the stock by cuttings, layers, and by division of the roots. Propagators succeed well with cuttings, making them in the Fall, and burying them in sand in the cellar, until April, when they are planted out in a light, deeply worked soil.

Chinese Grass-Cloth Plant (*Urtica nivea.*)—Mrs. Jane O'Brien, Allegany Co., Pa.: This plant belongs to the nettle family. It is an herbaceous perennial plant, growing about six feet high, and flourishes best in a moist peat soil. We do not know whether it will succeed in the Northern States or not. Will some one who has tried it please answer? The Rice Paper-plant belongs to the Leguminous or Pea family; its botanical name is *Sesechynmene paludosa*. This will not succeed in the Northern States.

Black Pepper.—"N. T. S.", Waldo Co., Me. The *piper nigrum* of commerce is a berry growing on a climbing perennial plant in the East Indies, and is too tender for this climate. Quite likely it might be cultivated at the far South. The *white* pepper is made from the same berry after removing the dark outside surface.

Leathery Fungus.—W. H. Woodward, Marathon Co., Wis. The curious piece of "vegetable buckskin" you send is a fungus growth, analogous to "spunk" used for tinder. The resemblance to sheep skin or buckskin in color, texture, and *odor*, is very marked.

Orchard Hedge.—S. B. Shaw, Ionia Co., Mich. Honey Locust, (*Gleditschia triacanthus,*) makes the best hedge to fence out trespassers. Boys, cattle, and other stock can not well penetrate through the long, strong, and sharp thorns. Plant in single rows, two feet apart, and cut back to within a few inches of the ground to establish a bush form. It will need frequent shearing.

Osage Orange Seed.—Several inquirers. Most of this seed comes from Texas, and owing to the suspension of intercourse with the South, no seed of last season's growth has come to this market. Thorburn of this city has some old seed, a portion of which will doubtless grow. Price 75 cts. per quart.

To Propagate the Holly.—W. R. Robbins, Suffolk Co., N. Y. The holly is not easily propagated. It rarely grows from layers or cuttings, and the seed often lies in the ground one or even two years before vegetating. Meehan advises to mix the seed with sand, and leave for one year, when the whole should be sown. Transplant when one year old, and once or twice afterwards, before their final setting out in May.

Apples in Cold Climates.—G. Y. Armstrong, Canada East. Surrounding the orchard with a belt of evergreens will be very beneficial in cold climates. Evergreens are sometimes set out in clumps in various places in the orchard itself. Plant only the hardy varieties of apples, such as Pomme Gris, Canadian Reinette, Roxbury Russet, Talman's Sweeting, St. Lawrance, Bourrassa, Danvers' Winter Sweet, Fameuse or Snow Apple, Ribstone Pippin, Rhode Island Greening, Red Astrachan, etc. We have named them in the order of hardiness; the last named is one of the best apples.

Wash for Fruit Trees.—L. T. Robbins, Plymouth Co., Mass., has used the following wash on his fruit trees for 20 years, and to good satisfaction, applying it early in June. Take equal parts of soft soap, clay and fresh cow manure, mix with water to a convenient thickness and apply with a stiff broom or brush. With a stiff corn broom he coats the large limbs as far as he can reach.

Field Beans for a crop in Young Orchards.—There is none better. Plant in hills or drills—if in hills 30 inches one way and 15 the other; if in drills, 30 inches apart and about 6 beans to the foot. The quality of the soil should decide in the manner of planting, if it be capable of producing a large crop, plant in drills. The Marrowfat field bean (white), or the common white bean are the advisable sorts. The former has a little tendency to run if strong manure has been applied.

Raspberries Failing to Send up New Canes.—A. Allen, Clinton Co., O. The principal cause of failure was allowing the enfeebled canes to ripen fruit the season of transplanting, after a long journey. The canes should have been cut down to 10 or 15 inches of the ground, when they would probably have thrown up new shoots.

Strawberries — Hermaphrodites Prolific.—F. M. Giddings, Ashtabula Co., O. It was formerly supposed that only pistillates were really productive, and a few nurserymen, like the one you refer to, still maintain that hermaphrodites can not bear abundantly. The Wilson, Austin, Hooker, Longworth's Prolific, Triomphe de Gand, Bartlett, Downer's Prolific, etc., all perfect varieties, entirely upset this theory.

Strawberries with Dwarf Pears.—W. J. Moore, Boyle Co., Ky. Your plan of planting strawberry beds between the rows of dwarf pears will answer very well for a time, if on good, rich soil. For list of desirable sorts see February *Agriculturist*, page 36.

White Turnip.—W. W. Johnson, Penobscot Co., Me. The white turnip you speak of as a good keeper, in shape and appearance like the rutabaga, is probably the Long White French, which we are distributing as a valuable sort.

Hybrid Turnip Seed.—"C. A. W." Hudson, N. H., writes: A carrot was set near a turnip of the round flat English variety. The turnip seed thus raised produced a crop, part of which were white as usual, and a part deeply tinged with orange. Had the carrot any thing to do with this? ..No. Some other kind of turnip grew within a few feet or rods.

To Keep Black Fly or Flea from Cabbages.—Sift on lime while the dew is on; sift on plaster, or flour and black pepper mixed, or ashes, or snuff; or strew tobacco stems through the field; or boil the stems, and sprinkle on the water; all these are recommended, and we have tried some of them with partial success, but hardly know which to recommend.

Sweet Potato Plants by Mail.—H. A. Lamb, Worcester Co., Mass. It is cheaper to send small parcels by mail, and they will go safely, if well put up. The expense of sending by mail is 1 cent per ounce. No more than 8 ounces can go in a single package.

Horse Beans.—S. B. Luckett, Wayne Co., Iowa. The horse bean is much used for stock food in England, where it flourishes finely. The seasons are too warm and dry for them in this country.

Sorghum Sugar Refinery.—Lathrop & Smith, of Oswego, N. Y., propose to put up an expensive sorghum sugar mill and refinery, if they can get a pledge that 800 acres of the sorghum will be planted this season in their vicinity. The refinery will cost $60,000 to $75,000, and preparations already made indicate that the 800 acres will be planted, and much more besides.

Good Lawn Grass.—The Kentucky Blue Grass, referred to in the October *Agriculturist*, page 292, appears all right. To-day (April 19) it presents a uniform green mat, while the Italian Perennial Rye Grass, near by, looks brown and much killed. We feel paid for waiting the slow—all Summer—starting of the Blue Grass. It will stand frost. One kind of grass, thinly sown, makes a prettier lawn or yard than any mixture can do.

Top Dressing for Pastures.—Bonedust and guano put on after giving the land a light scratching with a harrow, and then rolled in if practicable, or sowed on and left to itself, is a good dressing. Use per acre, 5 to 10 bushels of bone-dust, and 150 to 250 lbs. of Peruvian guano, *known* to be pure. On lands benefited by plaster, use it in such quantity as experience proves best in any neighborhood—from 250 lbs. to 500 lbs. to the acre. Unleached ashes are often capable of renovating pastures for a length of time. A single dressing showing marked effects after six or eight years. The quantity to be applied varies also greatly (from 10 to 30 bushels), and none can advise with accuracy; on light lands use less than on heavy clays.

Salt for Chimneys.—The *Allg. Deutscher Telegraph* says that chimneys built with mortar containing salt will require no sweeping, and be free from danger of catching on fire. An instance is given of a chimney thus built thirty years ago, which has never needed cleaning, and has never burned out. It is claimed that the salt gradually dissolves in damp weather, and carries the soot as it runs down. This may answer where wood is burned, but from coal fires the ashes or "soot" consists mainly of fine dry ashes, which would not be affected by the salt, even supposo enough of it would flow from the morter to dissolve anything.

Weeds and Dirt.—Johnson's definition of dirt, is "matter out of place," which is broad, and perhaps accurate enough. To weeds have been applied a similar definition, viz.: "Plants growing out of place."

Silk Weed.—J. P. Cawley, Salem Co., N. J. The pod containing the delicate silky egret, or hairy down, is from the *Asclepias cornuti*, or milk weed. Attention has been directed to it for giving a silky gloss to fabrics, It is said with some success. It may answer some purposes, but the fiber is too tender for spinning, we judge.

Eradicating Alders.—Ed. West, Stafford Co., N. H. We have cleared the Black Alder (*Alnus incana,*) from swamp land by cutting off a few of the roots and winding a chain about the clump, near the roots, and hitching a strong pair of oxen to draw them out. Begin upon one side, and make clean work as you proceed. It can be done quite expeditiously.

Manurial Value.—P. H. Foster, a Long Island farmer, put us a hard question. "What is the actual value for manure of various substances, taking the price of a bushel of corn as a standard?" Let us take barn-yard manure. On Long Island, and throughout the Eastern States, it is called worth $1 for a load for a pair of cattle—that is 1 load=2 bushels of corn. In Illinois, manure is considered worth less than nothing in many places, and corn 10 to 20 cents per bushel. You see we can not compare them.

An Aged Hen.—"Subscriber," Carlisle Station, O., writes, that he has a Prussian hen raised by himself in 1841, which makes her 21 years old. She is of a clear white color, medium size, was a good layer and successful in raising one or two broods of chickens every season, until the past two or three years. She still exhibits a maternal care over the broods in general.—Is not this the oldest hen on record?

Poultry Experience.—"Hampton," of Holyoke, Mass., writes, that many years ago, while yet a boy, he began taking the *Agriculturist*, and derived many hints from it, which he has been practicing upon since he has grown up, and here is *one* of the results: For fourteen years he has kept poultry, and considers them the most profitable stock in his farm. They have seldom failed to give him fresh eggs daily through every Winter. They have a light room, with a window facing south, boards on one side, and laying boxes on the other. They have a box containing ashes and old mortar pounded fine, to roll in. When the ground is frozen, they consume finely broken oyster shells and bones freely. Their main food is corn and oats mixed, as much as they will eat, twice a day, with occasional change to scalded meal. Once in a week during Winter, when insects are inaccessible, the fowls receive a little fresh meat. With the above treatment they have kept in good condition, and 15 hens, have given 4 to 8 eggs a day during the entire Winter.

A Good Scare-Crow.—The various works of art which we annually see in corn-fields do not please the taste. The following is an old one. "Take corn, and string each kernel on a horse hair—white is best—tying a

good knot in it to prevent its slipping off. Scatter these enticements in various parts of the field where crows and black-birds are wont to alight. No crow will eat more than one or two kernels in that field or any other very soon. The two ends of a horse-hair sticking out of his mouth, well anchored in his mawe by a fine kernel of corn, will be nothing of a pleasure to him, and he and his company will leave for parts unknown."

Plans for Bird Houses.—(Charles.) No, Charley, we have none, in our portfolio. But you, or your father, or the carpenter, can contrive something suitable. The Indians, you know, hang up calabashes on the sides of their huts, or on trees close at hand, and the birds soon occupy them. Almost any kind of box will answer; the birds are not fastidious about styles of architecture. But if you can make a little house, resembling in its outlines the house you live in, it will show some skill and taste on your part. A neighbor of ours has made a little Gothic cottage, a miniature edition of his own residence, and the birds like it. Another man, near by, has lately made a sort of Chinese pagoda, an octagon about 18 inches high and ten broad, and set it up on the top of a pilar twenty feet high. The blue birds have already begun to make reconnoissances about it, and will ere long take full possession.

Pepper *versus* **Rats.**—A subscriber recommends to fill the holes of rats with colored cotton sprinkled with pepper.—*Query*: Do rats dislike pepper, and if they do, will they not immediately dig new holes, and thus do more damage than if left to go freely into their old haunts? Their destruction is the only sure remedy—but how to secure this is a puzzling question.

Cotton Wadding *versus* **Cucumber Bugs.**—Take cotton wadding, cut it into pieces 8 inches square, split it, spread one piece glazed side up over each hill, just as the plant is coming through the ground, and pin it fast to the earth, with a sharp stick at each corner, a wire will do as well. This will do to keep the wind from blowing it away. This practice J. Banister of Essex Co., N. J., assures the *Agriculturist* "will keep all bugs off, and protect the vines from slight frosts. The protection is perfect, the result satisfactory, the cost trifling; and the crop will or may be two weeks earlier than it can be without this protection."

Coal Tar for Moles and Cut-worms.—"C. C.," Jamesburg, N. J., alluding to doubts stated in a recent number of the *Agriculturist*, says that he really *eat* peas, says, that however that may be, they *destroyed* his crop, at least, for two years. Last season he soaked the peas in a week solution of coal tar—a teaspoonful of tar to a quart of water—and the moles did not disturb them, though at work elsewhere in the garden. A neighbor drove them from working in his sweet potato hills, by pouring a little of the tar water in a slight trench around the plants. It was also tried around tomato and cabbage plants, and the cut worms did not trouble them.

Old Horses.—"Senex." Some horses are old at ten years of age, and some not until twenty. It depends chiefly upon the way they have been treated. The prevailing impression that a horse necessarily begins to fail after nine years of age, is a mistaken one. A horse does not attain his full growth and perfection of physical power till past his seventh year. He does not begin to run down right away. If he is not overstrained with heavy loads, or over-driven, or misused in any way, he will be in his most serviceable condition between his seventh and fifteenth years. For a family horse, or a safe saddle horse, or for real valuable service on the road or the farm, give us one who has sown his wild oats, and is content to be sober and quiet.

Glanders in Horses.—S. B. H., of Lumberton, N. J., in reply to the article on page 44, February *Agriculturist* says: He does not think by the symptoms that the horse has the glanders, but rather *Caries* of the teeth. The horse should be examined, and if the teeth are found to be decayed they should be extracted. Caries are often taken for glanders, and a person should be very careful to examine the teeth before resorting to severe treatment for glanders.

Points of a Horse.—"M.", of Malden, Mass., and others, will find illustrations on page 11 of vol. 18, (1859,) showing the points of a horse, both in skeleton and covered with muscles. We can not repeat them now.

Cattle—81 More on Each.—An intelligent observer, not himself interested in raising or selling improved cattle, writes to the *Agriculturist* from Hartford Co., Conn., that he doubts not the influence of the State Agricultural Society, and of the late Homestead, have together raised the value of all cattle in Connecticut an average of $2 per head; and he well says: How large would be the aggregate profit, if the average value of all the cattle in the United States were increased in value only $1 per head. Yet this increased value, and more, will be secured so soon as farmers understand the result of even a slight admixture of improved blood.

Garget or Caked Bag.—A. A. H., of Hillsboro' Co., N. H., communicates to the *Agriculturist* a simple remedy that, he says, will cure a cow in nine cases out of ten, if applied as soon as discovered, or very early. Bathe the bag in cold water for 30 or 40 minutes. Two applications (night and morning) will effect a cure.

Wrong Side of the Tree.—A subscriber in Stark Co., Ill., suggests a friendly criticism on the vignette of the February *Agriculturist*, viz.: that the man begins to cut on the wrong side of a leaning tree; he thinks "the artist at least was not brought up in the woods."—Precisely so, but we claim to know better, having felled many hundreds of trees with our own hands. (The "*we*," here includes several editors.) The picture was designed merely as a pleasant sketch of a scene common in the western wooded countries, and not to illustrate the particular method of felling trees. We acknowledge the criticism, and say to all novices when cutting down leaning trees, make the first cut, a largest notch on the side the tree is to fall, which will prevent its splitting upward.

Coloring of Autumnal Foliage.—"Mary" thinks, as do many others, that the beautiful coloring of the leaves in the Fall is caused by the frost. Doubtless King Jack hastens the painting somewhat, and dashes in some of the most vivid tints. But that is all. Did you not observe, last Autumn, that the trees were dressed in their most gorgeous robes, and that, too, before there was scarcely any sign of frost? The transformation was gradual, and therefore less striking than when it is the work almost of a single night. This change in the color of the leaf we must therefore ascribe to its ripening, rather than to its freezing.

Soda, Saleratus, etc., in Cookery.—A. M. Ward, Hartford Co., Conn., writes: "Four years ago I forbid the use of *Soda* and *Cream of Tartar* (doubtless saleratus also.—Ed.) in my family—we had spent money by hundreds of dollars on our teeth, but a *soft rot* ever made bread better. Now for two years past, a "toothache" has been unknown in our circle. I have two children, the oldest 5½, and neither has a tooth blemish. At first my wife said 'You can have no cakes now, nothing made of flour, but plain bread, and even that *uncertain*,'—but we have no lack of such luxuries, good in quality and variety. In my receipt book I discard *any* and *all* receipts having the above articles incorporated; and as a humane medium I would like to see the same stand occupied by the *Agriculturist*." (On the other hand, we could speak of the good resulting from the use of soda as a tooth wash. Chemistry does not indicate the unhealthfulness of moderate quantities of soda and cream tartar. Soda is an alkali, and neutralizes the action of acids in sour foods. Tartaric acid can be no more hurtful than the grape juice from which it is derived.—Ed.)

Botanizing Boxes and Bags.—"J. A. G." On page 276, Vol. XX, we mentioned an India rubber bag for carrying flowers; doubtless oil silk would answer. The flap must be made large to prevent circulation of air; the fabric light, and when filled it must be carried in a tin or other box. Delicate flowers are best carried and kept from wilting in corked bottles with a few drops of water, and straws enough to prevent their falling from one side to another. A good, close shutting, tin box, oval, 6 or 7 inches wide, 3 or 4 deep, and 12 to 14 long, opening on the side, and having a compartment at one end for water plants, with a cover like that of a pint pail, is a convenient form of botanical box for common use.

"Land Poor."—A subscriber who read the article with this heading, published on page 337, last volume, says it was intended for him, and that he shall take immediate steps to reduce his cares, expenses, anxiety, labor and taxes, by disposing of a portion of his land and improving the remainder. He is no longer going to be a slave to the title of "large possessions."

One Man's Complaint.—Among all the good words said to and for this journal, it would be strange not to have a complaint now and then. If done in a right spirit, we think most of those who tell us of our faults as well as of our good deeds. Here is a complaint we do not like: Mr.——— writes that "he can't endure the *Agriculturist* any longer, because it uses the imperative mood." [This man has studied grammer, and understands *moods*.] "The paper continually says 'do so,' or 'do so,' and I don't like this imperative tone...."—Well, well, must we give up our most cherished plan of putting a good many thoughts into a paper that can be afforded cheaply?—we do not like to have the appearance of haughtiness It is briefer to say: "Look out for slippery paths in the cow yards; spread some manure on the asparagus bed to keep it from freezing deeply; put a few bundles of straw around the pump when liable to be frozen, etc." But must we needs say: "It is respectfully and reverently suggested that the reader should look out that no slippery places be left in the cow yards; we respectfully and humbly suggest that the reader will find it advantageous to put some manure on the asparagus bed to keep it from freezing too deeply," etc. Why friend, we are in favor of the utmost suavity in talking to members of this free and republican country; but it is so much *shorter* to use the "imperative" form to convey the same idea, that we beg the privilege of continuing it *so as to save room for more hints*.

Okra Seed for Coffee.—S. Ransom, Warren Co., Ill. The seeds you send are *Okra*, (not Oker, as called in the Chicago Tribune.) For culture see April *Agriculturist*, p. 101. The plant is very common, and the seed abundant—on sale at all our larger seed stores. We have heard of the dry seeds being used for coffee, but have not tried them, and do not think they are of much worth for this purpose. The green pods are excellent for making soup—called "Gumbo Soup" at the South. We grow it for this from seed sown every Spring.

Illinois Coffee.—Peas $1,240 per Bushel.—Cautioning our readers against coffee humbugs, (page 101,) we called upon Mr. Huffman, of Illinois, to make some return for the $1.06 sent him. In justice we will say, that three weeks after the money was sent, we received a package of *53 chick peas (Cicer arictinum)*. They cost just *two cents* each, and we presume they will make as good coffee, as any other *peas*. Printed directions for culture, etc., accompanied them. Now, although the pods yield but *two* peas each, we think, judging from our own crop the past season, Mr. Huffman has made a good thing out of an old pea, not unfrequently sold by our seedsmen during the past 20 years.

Patriotic Farmer's Club.—The Club at White Plains, N. Y., (Henry C. Field, *Pres.*, Sol. A. Haviland, *Sec.*, Jas. Gibson, *Treas.*,) at their meeting April 9, adopted patriotic resolutions, giving thanks to their brother farmers and others, battling nobly and bravely in the service of their country.

A Snowy Country.—The Maine Farmer states that a severe snow storm entirely covered a house in the town of Mexico, (Me.,) burying two families, who were only relieved by the neighbors tunnelling through 40 feet of drift until they reached the front door. If "snow is the poor man's manure," Maine should be a fertile State.

Rain in California.—Apropos to the above is the amount of rain which fell in California and Oregon during the past Winter. According to the California Farmer, over 35 inches of rain fell in San Francisco from the 10th of November to the 23d of January. The average quantity of rain in that vicinity is about 20 inches annually, while here, in the vicinity of New-York City it is 55 to 60 inches.

Cheap Sewing Machines.—A Babcock, Union Co., Ill. All these small "pocket" machines, which are screwed upon a dining table or stand, and work with a crochet hook or needle, are altogether too cheap, or rather dear, at any price, whether it be $5 or $10. We know purchasers who would be glad to re-sell their "cheap machines" for $1 or less.

Manure Book Wanted.—Several subscribers inquire for a good book adapted specially to the use of manures; and one, of a seeling told that there is no such work, complete and reliable, suggests that some practical farmer or competent chemist would benefit others and his own pocket also, by getting up such a book. We do not know any one man capable of writing such a book in the present state of our knowledge on the subject. There are too many unsettled theories as to the action and value of different kinds of organic and mineral manures. In a series of articles given in the *Agriculturist*, Vol. 19, (1860), we tried to set forth our own views, so far as confirmed by experience—with some theory.

Soda Crackers.—We published in 1860, the method for making soda crackers. It is hardly worth while to repeat it, for it is very difficult to make them in private families so that they will resemble the bakers'. A sponge is set over night, and the next morning stiffened with flour, butter or lard added, and the whole well rubbed together and beaten, and finally rolled out, cut, and pricked as we see them, and baked in a brick oven.

The Agricultural Bureau—Who Shall be at the Head of it?

Letters from Washington assure us that the House Bill for the Establishment of an Agricultural Bureau, will certainly be passed in the Senate and become a law. We were at first inclined to favor its passage, even with its objectionable features. But we can not do so, and for this reason. Within the last three weeks we have received ever so many letters from parties (and their friends), who are lobbying the bill through, because each one of these parties has a *personal* interest in the matter—each one is expecting to be placed at the head of it with the comfortable salary of $3,000 a year. Some of them are our personal friends, good, honest men, too; and we especially dislike to forfeit the good will of those who privately promise that the *Agriculturist* shall lose nothing if it will only advocate their individual claims. How can we do so for *each*, if the interests of agriculture compel us to say frankly that we do not believe one of the applicants now seeking the appointment of Commissioner of the proposed Agricultural Bureau would, if successful, be "the right man in the right place?"

If the proposed Department, or Bureau of Agriculture, as a part of the Government of the country, is to amount to any thing, it must have at its head a man of no less breadth of mind and capability, than is required for the other Departments of the Government—added to which he should have the *experience* of a large cultivator. The trouble in the past has been, that the sub-Secretaries in the Department of the Patent Office allotted to agriculture, have not been first or second class men, but mainly fifteenth rate inefficient fellows—such as D. J. Browne, Lee, Clemsen, etc. We could name a dozen men among the reporters of the city press, two dozen or more city or country editors, a hundred country-bred clerks in our city stores, and two hundred officers of our Agricultural Societies, any one of whom would be better fitted to conduct the Department of Agriculture than several of those who have had most to do with that interest in Washington for half a dozen years past. We will guarantee to send out from the *Agriculturist* Office at least five men who would conduct the seed distribution, and other matters, in the wing of the Patent Office, and collect and diffuse more valuable statistics, and even get up a more useful "Annual Report" than anything that has emanated from Washington, since Commissioner Ellsworth's day.

But we want, farmers want, the country wants at the head of the proposed Agricultural Bureau some such man as N. P. Banks, for example, who has had not only large experience as a cultivator, but has shown himself to possess administrative talent, a broad comprehensive mind capable of looking over the whole country, to take in at a glance the needs of agriculture, and the facilities for supplying those necessities. A fourth rate clerk can attend to the details, but eminent ability is required to direct what is wanted. Such men are to be found, and our great agricultural interests need their efforts, and afford abundant scope for their talents. There are many more men fitted to be governors of States, than there are to be placed at the head of a Bureau of Agriculture, in the Government of these United States—pre-eminently the greatest agricultural country of the world. We hope the President, or whoever may have the appointing power—if the proposed Department be organized—will weigh the matter well, before filling so important an office. It is not our province to nominate candidates. We named Mr. Banks merely as an illustration of the kind of talent wanted. We see that the Saratoga Press, in a recent editorial, and two or three other journals, nominate the writer of this, for "Chief of the new Agricultural Bureau." With thanks for the friendly spirit shown, we beg most respectfully to decline any such nomination—even on the intimation that "if we dont take the office, somebody less well qualified will." We don't begin to possess the ability of the man whom we would have placed at the head of such a Department, and if we were vain enough to suspect we had, our present position is abundantly satisfactory for our ambition, and is only second in importance to an agricultural Bureau. Every day we feel our own incompetency, and would be happy to call to our aid some one who can make the *Agriculturist* even a better promoter of the agricultural interests of the country than it now is. We would gladly surrender the editorial pen entirely to more competent hands, and devote ourself wholly to the necessary pecuniary or publishing interest—as a "hewer of wood and drawer of water."

We trust the views set forth above will be a sufficient answer to those who have done us the honor to solicit the influence of this journal in aiding them to secure a place at the head of the Agricultural Bureau—proposed. We care not who secures the office, if he be an honest man, and fully *competent* to perform its duties.

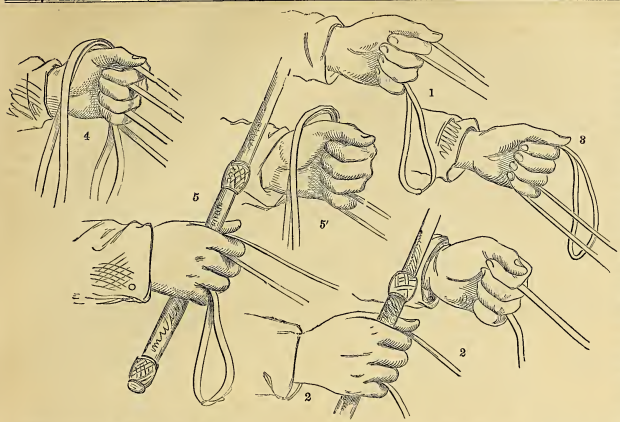
Rotation of Crops.

There are various arguments for the practice of raising different kinds of crops in succession upon the same piece of land, now common in the older parts of this country. These arguments are based both upon practice and theory; the former being to most of us the more conclusive. Long ago it was discovered that much land would bear a good crop of grain only once in two or three years without manure, and that to secure a crop, it was necessary to plow or otherwise work over the land in the mean time. This system of *fallowing* necessarily left the land at least half the time with no crop upon it, and the farmer depended for a crop upon the decompositions wrought in the soil by the action of the elements, aided by his own labor in overturning and pulverizing it. When it was discovered that a crop of roots could be raised between the crops of grain, and the effect of fallowing still be realized, the roots were regarded as clear gain, and the whole system of farming was changed. Now, on all those lands where farmers are obliged to be economical of fertility, some system of alternation or variation, if not a proper rotation of crops, is employed. It is enough for most farmers to know by experience that—whether they depend on the fertility of the soil alone, on the green manure which they plow in, or on the dung of cattle which they apply—they realize by this means a much better return for the time, labor, and available fertility expended.

Some crops seem very rapidly to exhaust fertility so far as they alone are concerned; and the theory of many is, that this exhaustion results from their appropriating the most available supplies of certain substances essential to their growth. Other crops either use less of these substances, or have the ability to collect them more easily. Thus turnips, though they remove from the soil a comparatively small quantity of the phosphates, yet an abundant supply in a very available form promotes their growth and increases the yield, in an entirely disproportionate degree.* And wheat and other small grains demand a proportion of available nitrogen greater than other crops which remove more from the field. The benefit of an alternation or rotation of crops being a recognized fact, and it being also true that under certain ill-judged modes of farming land became unaccountably *sick* of certain crops which before grew well, M. Decandolle proposed a theory which met the case, and was almost universally received. It was that the roots of the crops throw off, or excrete substances in the soil (which is true), and that these substances while injurious to the plant which throws them off, are food for other kinds of plants, (which, at least to any appreciable extent, is not true.) Still it very simply and fully accounted for the facts as then known.—Almost all plants have their natural enemies, parasitic plants, like smut, rust, etc., or insects which live upon them—and when a plant grows several years in the same soil, it becomes more and more a prey to these, and perhaps subject to other diseases having similar but not so obvious causes. In this view of the subject the excretory theory may find legitimate application.

When the full value of manure is realized, practice has demonstrated that crops must follow each other in the order of their dissimilarity—for instance: grain, roots, grass, leguminous plants (peas, beans, clover seed, etc.); oil plants, (colza, rape, poppy, flax seed, etc.); and commercial plants raised for the plant itself (tobacco, hemp, flax, madder and other dye-stuffs, etc.) The longer the time intervening between two crops of the same plant, the better. Rotations are usually short in this country, and the land manured but once. In other countries, rotations continued through ten or twelve years are not uncommon. One reason for this is, that in our market there is not a demand for so many products, though this evil is rapidly diminishing. Different soils and different markets make different crops profitable. The culture of Indian corn in this country is so different from the other cereals, that it is classed by itself, or with potatoes, though potatoes will not bear the manure that corn will, and in this respect, tobacco and corn are similar, and may occupy similar places in a rotation. Where the clover and wheat alternation is practiced, good crops may be raised several years without manure; thus: wheat on clover sod plastered and seeded down with clover; the next year clover fed or cut; third year clover pastured in Spring, and clover sod turned under and wheat sowed. Some land improves for a while under this system, but there is danger of its becoming clover sick, and refusing both crops. Another ill-judged rotation is: corn on sod with manure, oats, wheat with bone-dust, superphosphate or guano; and finally grass. Corn with manure, oats; clover, wheat, grass, is much better. Corn or tobacco, roots, spring grain, clover, wheat, grass, is still better, and for many parts of the country a good practical rotation. The wheat will be benefited by a special manuring in many cases, and the roots may receive the bulk of the manure plowed in in the Fall after the corn is taken off, —the corn being made to depend in a great measure on the sod turned in. W.

* It may be considered still an open question, whether the beneficial results arising from the use of soluble phosphatic manures are due to the direct absorption of phosphoric acid as plant food, or whether this acid does not act mainly as a powerful absorber and retainer of ammonia. So also it may be questioned, whether less of the costly phosphoric acid, and more of the cheaper sulphuric acid may not be productive of equally good results. O. J.



Driving Horses—Holding the Reins.

Many a fatal accident has occurred, with good steady horses too, from the driver having a loose or awkward hold upon the reins just at some critical moment. Not only must his attention be upon his horses, and his eye schooled to notice the least unusual motion of their heads, ears, or gait, any loosening of a buckle, or slipping of the harness, but the reins must be so thoroughly in his grasp that at all times the team is fully under his control, and not only so, but conscious of it themselves. A weak, uncertain hold upon the lines gives a wilful horse a sense of unrestraint, a timorous one a lack of confidence in his driver, a shying, frisky, nervous beast all the excuse he wants to turn a summerset or ent some other caper. Herbert, (Frank Forrester,) lays great stress upon the *manner* of holding the reins, and we employ sketches in his "Hints to Horsekeepers," to illustrate the subject. There are two methods generally approved; in both the reins are commonly held in the left hand, and the off-rein passed into the right hand whenever necessary. This must often be the work of an instant, and so in whatever way the lines are held, the nigh-rein must not be in the way, nor may the hold upon it slacken. In the engraving at 1, the off-rein is seen to pass over the fore-finger, the nigh one under it, and both out between the ring-finger and little-finger. The right hand takes the off-rein, as seen in 2 and 2', while at the same time a firm grasp is had upon the whip. At 3 we see another method of holding a single pair of reins, the off-rein in this case being between the ring-finger and little finger, and the nigh-rein below, both ends passing out over the fore-finger, beneath the thumb. This is not so strong or easy a hold. The method of holding the reins in four-in-hand driving is illustrated at 4, 5 and 5'; 4 shows the left-hand holding the four reins, the off-reins being the upper ones, the ends passing down through the hand; and the nigh-reins held as both reins are in 3, the ends passing up, and over the thumb. When taken in two hands, the nigh-reins remain unchanged in the left hand (5'), and the off-reins are passed into the right hand (5), and held as in 1. In whatever way the reins are held in driving, the driver should be so familiar with them that he can, without giving a thought to it, as quick as thought, change or shift them about, and never slacken his hold or lose perfect control of his horses.

Washing and Shearing Sheep.

The object of washing is to cleanse the wool from the yolk or gum which is an oily soap secreted by the skin, as well as to remove any other soluble dirt from the fleece. The hard balls of filth which adhere to the wool will remain in spite of the washing, and if soaked often stain the adjoining fleece. In those sheep whose wool abounds in yolk, as the Merino, the shearing is much facilitated by washing, and in all kinds the wool is whiter, cleaner, and presents a better appearance. The objections to washing are, that unless extreme care is used, accidents will happen to the sheep, and this loss more than balances the gain to the owner. Even with care, colds and catarrh ("the snuffles") almost uniformly arise from the sudden chilling bath, and the health of the sheep is often permanently injured. Without washing, sheep may be safely shorn ten days to three weeks earlier than when we have to wait for the weather or water to become warm. At this season many will be shedding their wool, especially ewes with lamb, and a large share of the fleece is thus sometimes wasted. The loss for a few month's time embracing the last of May, and first of June, probably equals or exceeds the growth for the same period, so that one twelfth, at least, is wasted.

To get the greatest yield of wool for the year we should shear early, without washing. This is also a saving of labor, for the labor of washing more than balances the extra trouble of shearing them unwashed, and it also secures the health of the flock. But on the other hand, buyers insist on deducting one third for unwashed wool, and the quality appears hardly as good as it really is. Most kinds of wool do not shrink one third by washing on the back of the sheep, but farmers will continue to roll up in their unwashed fleeces what really belongs to the dung-hill, so that perhaps it is not, on an average, too large a deduction. The best flock masters in many sections, are generally discontinuing the practice of washing; and breeders of very valuable sheep very rarely, perhaps never, subject them to the operation. If a sheep is worth $100, the risk to his life and health is too great, and it is safe to say that in a flock of which it will take 20 sheep to be worth $100, the risk is decidedly greater, or rather there is almost an absolute certainty of some essential damage to the flock by colds contracted, etc. Sheep washing as practiced by the best farmers is on this wise: A morning is selected as early in June as the weather is warm enough not to chill the washers or sheep, immediately after a good rain. The sheep are then well soaked, and half the labor is accomplished. There is no dust on the roads, and the sheep may return clean to their pastures. A pen made of boards or hurdles, just large enough to hold the flock and so high and firm that they can not possibly escape, is upon the bank of a clear brisk stream. A dam of a few feet in hight raises the water so that it flows in troughs and falls with some force upon the sheep held by the washers in a pool below, where the water is just deep enough to swim the sheep. By coaxing with salt and gentle driving, the sheep are gathered in the pen. All *rudeness* in driving and in handling is avoided; when once frightened they are very difficult to manage. Two men go into the water to wash, a third catches the sheep, and a fourth helps them out of the water. If they have not been well tagged before, it should be done before washing, for the water will not remove the hard lumps of dung. The sheep must not be held by the wool, except about the head, for it pulls out very readily at this time. The washers hold the sheep under the falling water, squeezing the wool until the water runs away clear. It is surprising to see how quickly the fleece of a sheep, well soaked by a previous rain, is cleansed.

Of all farm operations, sheep washing most needs "*the eye of the master.*" In the excitement of the rude scene, the flock are liable to abuse, and too often from crowding in the pen, heated from over driving, or rude handling, serious losses occur; and sheep are not unfrequently found in the pen dead, or in a dying condition. They must be driven slowly from the washing to a clean pasture. The whole operation is a most distressing one to the sheep, increased almost uniformly by the roughness of the men, the best of whom seem to think a fine sport, and show no tenderness or humanity in their handling of the poor frightened beasts. In about a week, if the weather is dry, they will be ready for shearing. They must not only be perfectly dry but the yolk must flow so as to give an oily softness to the wool. The barn floor is usually used for shearing, and must be repeatedly swept as the fresh shorn wool is easily soiled. Careful shearers, who will neither waste the wool by cutting it in two, nor wound the sheep, though this care makes them slower, are to be preferred to those

who eut and slash to do a great day's work.

In doing up the fleece, the inner side of the wool must be out, and there must be no concealed dirt within. The shrewd wool buyer buries his nose in the snowy fleece, like a dog after game, and external purity will not serve to conceal dishonesty and filth lurking within. Before the sheep are turned away they receive the owner's mark upon the side. Use a mixture of spirits turpentine, linseed oil, and lampblaek. Turpentine facilitates the drying, but used in excess, the mark washes off too easily. The tar bucket must be on hand, and a dab on the nose is supposed to be a sovereign remedy to prevent all future ailments. With fine wool sheep which lamb in May, doeking and castrating the lambs may be performed at the time of shearing, but if the lambs are earlier it may be best done while the weather is eool. They suffer less while they are small and there are no flies to attaek the wounds. The tail should be cut off at the first joint, leaving the skin long enough to cover the stump.

Notes on the April Agriculturist.

BY A WESTERN FARMER.

"*Patent Office—Agricultural Department.*"—A humbug—and nothing else! as it has been heretofore conducted. Abolish the thing at once, or put a sensible, honest, agricultural man at the head of it. Instead of the charlatans who have occupied it pretty much ever since it was established. Its books have been—trash; its seeds, nine out of ten—worthless. A Congressman's "tub," to his constituent "whale." I could talk an hour about it to prove my assertions, were it necessary to establish the proof. I hope Congress will not vote another dollar to support it, unless the whole thing is thoroughly reorganized.....

"*Hints on Tobacco Culture.*"—Folks will chew and smoke and snuff—talk as much as you please of their immorality, unwholesomeness, and expense... As for the *nastiness* of the habit, let those whom it troubles, settle it. At all events, tobacco is used as much as ever, and probably will be so long as the users can get the means to pay for it. Such, then, being the fact, let those who grow the weed, produce the best article, and at the cheapest rate.....

"*Where did it Come from?*—A most suggestive article. A chapter occupying half your paper might be written on it, and not half exhausted. Some years ago, a certain Doctor, editor of one of our agricultural papers, and late an editor of a Georgia paper of like character, used to hold, that according to the system—or rather, no system—of our American agriculture, our soils were 'all going to pot.' The fact is, our soils, where they have been thirty, or forty years under intelligent cultivation, are growing better. But it is too long a story, and if I once go into it, I shall not know where to stop. Any thinking man can eypher out the reasons to support any asserted *fact*.....

"*Chester County Pigs.*"—A good breed of *large* hogs, no doubt. But why "Chester" County? I assert, and ask for proof to the contrary, that they are nothing but a composite *style*, not *breed* of hogs, made up of Leicester, Yorkshire, and every other sort of stout, good-looking white hogs that the breeders of them fancied as the *material* to make up the thing they choose to call "Chester County." Show me the pedigrees, accurately traced back to the originals, and then we'll talk further about it. I have seen the predominating characteristics of at least three or four good breeds of pig in the "Chester's;" some more, some less, but not uniform, either in the whole breed, or in a single litter. When I see half a dozen so-called thorough bred sows breeding from one boar a lot of pigs looking as much alike throughout as so many white kidney beans, I'll believe in the *purity* of their blood—and not before....

"*Value of Blood in Animals.*"—Yes. I believe in blood—in *folks*, even, as well as in cattle, pigs, or poultry; and breeders of stock will never get any thing right, and *certain*, until they pay attention to it. But what do you mean, Mr. Editor, when you say, "Our breeders of thoroughbred cattle, of all the improved breeds, commit a great error in holding their bull calves at so high a price as to prevent sales, and finally, as is often done, making stags of them rather than sell them at a low price. If they would even give away the bull calves which they do not wish to keep, and which are not worth a very high price, on condition, &c." A total mistake, Mr. Editor. Cost nothing, worth nothing. If a man can see no better quality in my bulls and cows, which cost me two, three, or five hundred dollars a piece, than in his own dirty scrubs, and dunghills, worth twenty, he is not fit to have one of them. I've tried all this thing for thirty years, or more, and know just what it amounts to. No Sir; my experience is—and I am not called a stingy man, either—I'll make meat of a calf, pig, sheep, chicken, goose, duck, turkey, or pigeon, before I'll *give* the first hair, or feather of either to one of those unappreciative non-improvers, who will insist upon it, that, unless he can beg, borrow, or more likely, *steal* the services of my male thoroughbred things, his own plebeian wretches are as good, or a little better than mine. Just practice on your own advice a year or two, and if you don't change your mind, I'll say that myself, and not you are mistaken.

"*Six best Shade Trees (Deciduous).*"—You have *not* got the "six best," Mr. Editor. The "White Elm" is good—the best of any—grand, thrifty, and enduring. The sugar maple is good, but too symmetrical, and formal, for picturesque effect. Yet I would have it, in moderate numbers. The several varieties of white, red, and other *soft* maples are better. They are hardy, thrifty, and throw, and dash, and wave their spray around with a freedom and grace that the *sugar* maple knows nothing about. I would have at least three of these *soft* to one of the *sugar*. As to the "oaks"—among shade or lawn trees they are like our American Indians when allied to civilization. The association kills them. The oaks, compared with most other of our native forest trees, are not hardy. They are difficult to transplant, and live, they grow comparatively slow, when they grow at all. They leaf out late, and have little beauty in their autumnal garniture, which I think a great merit in all shade trees. Still, a few well selected oaks, scattered in with other trees, look well, for variety; but I would recommend no one to plant a *row* of them. The "majesty, and grandeur" of a full grown *white* oak I eoncede; but as for the timber, they are better grown in a forest. I've grown thousands of them, and have them now, from the one-sized sapling to those fit for the keel of a ship. *My experience* is: plant them *very sparingly* as shade trees. The "Linden"—good—either the European, ("*Tilia Europa*,") or the American "Bass wood." They are beautiful, grand, and stately; early to leaf, and late to fall; easy to transplant, and thrifty to grow. The "white ash" is a noble tree, but too late in leafing out, and too early to shed in the fall. Still, for a variety, I would have a few, only. Like the oak, a valuable timber tree, and better in the woods than elsewhere. The "Cucumber" is a fine tree—when you can get it—but it is difficult to grow, and if in a *windy* position, very apt to grow one-sided. Yet, one, or two for variety are well enough. Better fill up your other varieties with Birch, Willow, and Horse Chestnuts. The Tulip, or white-wood is a noble tree, of good symmetry, but a hard one to transplant and live, unless reared in the nursery. I never yet saw an avenue, or row of them, even in a white-wood country. Another thing: they will thrive only in a free, well drained soil. "Buttonwoods" are all diseased, and have been throughout the United States for the past thirty years. I know of but one truly *healthy* one within miles of my home, and I have many on my own grounds—cutting them away every now and then for the reason of their diseased unsightliness. As to the *nut*-bearing trees you name, be sure they will be protected from the ravages of "the boys," or the vexation of losing their fruit is more than they are worth. They are all hard to transplant, successfully. The American Chestnut is a princely tree in size and appearance, and we have scarcely one more useful. The beech is refractory to transplant; and the birch capricious in its choice of soils. A cool moist soil suits it best; White Willows grow every where, and Horse Chestnuts thrive in any tolerable soil, and are easy to transplant and live.

Advertisement—"*Something New.*"—"Dr. Brown's *patent* baby tending machine!" "Saves from $100 to $300 per year in any family where there is a baby!" Well; that will do—for an "Advertisement." Now, Dr. Brown, in that "saving" of $100 to $300 you tell a tough story! I know scores of families counting their children by the dozen, hardy as coons, and saucy as chip-monks, whose parents were never worth three hundred dollars, and never will be. Tough, stout, athletic youngsters—boys, and girls, as likely to be "somebody" in the world some day or other, as any body's children—and no "patent" about them either. A tree "gum" split in two, or ten feet of rough boards box shaped, with a hewed rocker under each end, and your "baby," after a full draft of a healthy mother's milk, is equipped in all its wants. Folks that don't know any better than to raise children at three hundred dollars apiece for a "baby jumper," may buy your machine. We don't do it in *our* country. JOSH.

Concentrated Manures, or Articles sold as Such.

We received just too late for our April issue, an article from Dr. Evan Pugh, President of the Agricultural College of Penn., giving the results of the analysis of several artificial manures. The analyses were made under his own direction, and all the samples except those marked in the table A, K, and L, were obtained by a responsible member of the Philadelphia Agricultural Society, from the respective manufacturers of each, or their agents, without their knowing for what purpose they were procured. Mr. Lawes sent Dr. Pugh a tun of his superphosphate (A), and half a tun of his sulphate of ammonia manure (K), and from these the samples analyzed were derived. We are obliged to condense Dr. Pugh's communication somewhat; the following is the main substance of it. We do not fully endorse all the estimates, but let the Doctor give his own views:

ESTIMATION OF THE VALUE OF MANURES, ETC.

Manures are mainly valuable for the *phosphoric acid*, *nitrogen* and *potash* they contain. *Sulphuric acid* is much less valuable, and other constituents may be neglected [in high priced fertilizers]. All these substances are much more valuable when in combinations soluble in water, than when in insoluble combination. Thus: potash in wood ashes, is more valuable than in powdered glass. Phosphoric acid, in superphosphates, is more valuable than in *raw* or *burned* bones. Nitrogen is more valuable in a salt of ammonia than in leather or horn. It is easy to fix a price upon all these substances by seeing at what price substances, containing known quantities of them, can be purchased in the market. We thus find the values of

Potash (as in wood ashes) to be worth about	4c. ₩ lb.
Phosphoric acid, insoluble (as in raw and burned *bone* phosphates.)	4½c. ₩ lb.
Phosphoric acid in combinations, *soluble in water* (as in superphosphates).	12½c. ₩ lb.
Nitrogen in combinations easily soluble.	17c. ₩ lb.
Sulphuric acid.	1c. ₩ lb.

Different agricultural chemists have assigned values varying slightly from the above,* which, with the exception of the last, were adopted by Prof. Johnson, of Yale College, in his able report to the Connecticut State Agricultural Society.†

In the statement of the analyses, the figures in the principal horizontal lines indicate the percentage composition or number of pounds of each ingredient in 100 pounds, and immediately below each is its market price. In estimating the selling price, the tun is regarded as 2000 pounds. Thus: in 100 pounds of Lawes' superphosphate (A), 13.77 lbs. 1

TABLE of *Analyses and Computed Values of Various Fertilizers.*

MANURES EXAMINED.	Volatile and Moist.	Nitrogen.	Phosphoric Acid, in Water, Soluble.	Phosphoric Acid, in Water, Insoluble.	Sulphuric Acid.	Insoluble Silicates (Sand.)	Selling price per ton.	Calculated value per ton.
A—Lawes' Superphosphate, (English)	30.78	.....	13.77	4.48	28.89	4.46	.....	$44.26
Value of Constituents in 100 lbs.			$1.72	$0.20	$0.20			
B—Rhodes' Superphosphate	46.18	.....	11.11	4.02	30.66	2.26	$45.00	$37.60
Value of Constituents in 100 lbs.			$1.39	$0.18	$0.31			
C—Berger & Butts' Superphosphate	19.75	.....	4.13	10.58	11.73	12.89	$45.00	$22.40
Value of Constituents in 100 lbs.			$0.52	$0.48	$0.12			
D—Baugh & Son's Raw-bone Phosphate	33.65	3.17	.05	10.52	18.18	5.53	$45.00	$33.50
Value of Constituents in 100 lbs.		$0.54		$0.47	$0.18			
E—Baugh & Son's Ground Raw-bone	40.55	4.49	.....	23.14	.96	.08	$35.00	$36.20
Value of Constituents in 100 lbs.		$0.76	.....	$1.04	$0.01	.....		
F—Tasker & Clark's Phosphoric Fertilizer	40.13	2.76	1.76	11.52	6.64	8.65	$40.00	$25.40
Value of Constituents in 100 lbs.		$0.47	$0.22	$0.52	$0.06			
G—Tasker & Clark's Meat and Bone Compost	47.49	1.23	.....	9.43	.44	14.11	$25.00	$13.60
Value of Constituents in 100 lbs.		$0.21		$0.42	.....			
H—Mapes' Nitrogenized Superphosphate	25.31	1.35	.11	9.10	9.08	25.16	$50.00	$14.60
Value of Constituents in 100 lbs.		$0.23	$0.01	$0.40	$0.09			
I—Lodi Company's Poudrette	41.59	1.38	.....	6.80	6.96	28.66	$2.00	$11.40
Value of Constituents in 100 lbs.		$0.23	.....	$0.27	.07		per bbl.	
J—Rogers & Gest's Ammoniacal Superphosphates	94.71	18.96	.....	.....	57.34	.34	$45.00	$75.50
Value of Constituents in 100 lbs.		$3.22			$0.57			
K—Lawes' Sulphate of Ammonia, [English]	99.12	20.30	.....	.....	60.42	.....	.....	$80.50
Value of Constituents in 100 lbs.		$3.44			$0.60			
L—Peruvian Guano	64.25	14.98	.....	13.16	.....	1.78	$60.00	$56.80
Value of Constituents in 100 lbs.		$2.25	.....	$0.59	.....			
M—Government Peruvian Guano, [Philadelphia]	43.75	7.50	.....	12.98	2.46	18.34	$60.00	$37.60
Value of Constituents in 100 lbs.		$1.13	.....	$0.58	$0.02	.....		
N—Pacific Ocean Guano	23.31	8.75	.....	9.26	36.21	.42	$50.00	$45.20
Value of Constituents in 100 lbs.		$1.49	.....	$0.40	$0.37			
O—New Fertilizer	17.20	.....	.....	2.43	6.00	58.65	.....	$3.40
Value of Constituents in 100 lbs.			.....	$0.11	$0.06	.....		

soluble phosphoric acid, which at 12½ cents per pound—$1.72; 4.48 pounds insoluble phosphoric acid, at 4½ cents—20 cents, and 29 pounds of sulphuric acid at 1 cent per pound—29 cents; in all $2.21 per 100 pounds, or $44.20 per tun as given in the last column. To learn the value of a barrel of Lodi poudrette, weigh a barrel and multiply the weight by.57, and it will give the value in cents; when a barrel weighs 263 pounds it will be worth about 150 cents.

It will be seen at a glance at the 3d column, that only three manures analyzed are superphosphates; and the quantity of soluble phosphoric acid in Berger & Butts' is so small, that we can consider but 2 of them as genuine superphosphates. Tasker & Clark's fertilizer gives evidence of an attempt to make a superphosphate. The results in this column were obtained by boiling each sample in water 10 or 15 minutes. In the 4th column we have the amount of phosphoric acid existing in the form of raw or burnt bones. By the 2d column we may judge of the respective claims of the manures to the appellations "ammoniated," "nitrogenized," etc. Baugh & Son's manures, made from *raw bones*, show the superior value of this material over burned bones. In the one, 54 cents worth, and in the other, 76 cents worth of nitrogen to the 100 pounds are found, which would not have been present had burned bones been used in the manufacture.

The analysis of sample H, shows that a manure may be named and sold at a high price as an "Ammoniated Superphosphate" without having more than the most insignificant quantity of either ammonia or superphosphate in it. Such a name applied to such a manure expresses a dangerous falsehood. J, shows a large amount of nitrogen, but the manure coutains no phosphoric acid; the name therefore is false, but the manure is good. J, and K, are both sulphates of ammonia and as ammoniacal manures are the most valuable in the list. The two guanos are seen to vary greatly in value.

In the 5th column the amounts of sulphuric acid are given. This comes from that used in making the superphosphates, from that constituting a part of sulphate of ammonia, or sulphate of potash, or from adulterations of gypsum (sulphate of lime) or sulphate of soda. In the 6th column we have *sand*, or earthy matter insoluble in water or acids, and worthless. The last two columns enable us to compare the calculated values with the selling prices. C, D, F, G & H, are sold for about double their values, B, is the cheapest American superphosphate; but it is sold at $7.40 per ton above its calculated value. The most flagrant imposition of all of them is Mapes' so-called "Ammoniated Superphosphate." It is sold for nearly three times as much as it is worth. The manufacture and sale of such a manure deserves the severest censure, as implying either gross ignorance or dishonesty. No wonder that, with such a mixture in the market, farmers are often disgusted with the use of artificial manures.

We find Rogers & Gest's "Ammoniacal Superphosphate" (sulphate of ammonia) by far the cheapest source of Nitrogen; Rhodes' superphosphate the cheapest source of soluble phosphate, and Baugh & Son's ground raw bones the cheapest source of bone phosphate.

The attention of farmers and dealers is seriously asked to the consideration of the above facts. To protect themselves, they should demand that manufacturers guarantee their manures to contain a *definite amount of those elements of fertility upon which their value is dependent.* The evidence which a true analysis gives, is worth volumes of recommendations from those who have "tried the manure."

* Let it be understood that these prices are those established or adopted by most agricultural chemists, and *if* their estimate of the manurial *value* of the several elements be right, these calculations are correct. On this point *we* are not so well satisfied as are some. We still doubt as to the estimated value of phosphoric acid, whether "soluble" or "insoluble." That this element is valuable as a fixer of ammonia, with which it combines readily, is undoubtedly true; and the same, in a less degree, may be said of sulphuric acid. The *essentiality* of phosphoric acid as a constituent in plants, and the degree to which it may be needed in any soil as a specific manure, is another question. We have great faith in ammonia and ammoniacal manures; and for our own use would buy only those largely abounding in this element, unless they contained sulphuric and phosphoric acid enough to fix ammonia from the air in large quantities.—O. J.

For the American Agriculturist.

Annual Cost of Keeping a Horse.

Few farmers keep accurate accounts, or have any idea of the expense. Those who make a business of carting and have to purchase all their food, have the means of exact knowledge in their hands. Experiments conducted on a large scale, give the most satisfactory results, as they give a fairer average for single horses.

The Eighth Avenue Railroad Company in this City keep about six hundred horses, weighing on an average eleven hundred and fifty pounds, and consuming daily ten pounds of hay and eighteen pounds of grain—a mixture of corn and oats, ground. With hay at a cent a pound, and the mixed meal at the same price, the daily cost of each horse would be twenty-eight cents, making $1.96 per week—equal to $102.20 a year. The price of hay varies from ¾ to 1 cent a pound in this City, rarely getting above the latter quotation. The price of corn and oats is as often above as below 1 cent a pound. The Third Avenue Railroad Company keep eight hundred and eighty horses, of the average weight of eleven hundred pounds, which each consume nine pounds of hay, and seventeen pounds of grain. This would make the cost of keeping twenty six cents a day, or $94 a year. The Sixth Avenue Railroad Company keep five hundred and thirty horses, of the average weight of one thousand pounds, which average about six and a half pounds of hay, and fifteen and a half pounds of grain. This would be twenty two cents a day, or $80.30 a year. The horses on these roads travel from eighteen to twenty miles a day, and keep in good condition on this fare. It would seem from these figures that it costs twenty two dollars more a year to keep a horse weighing eleven hundred and fifty pounds than one weighing a thousand. Of course a farmer who wants a horse only for the road, and for light loads, should keep a light animal. For many kinds of business, a horse weighing nine hundred pounds is just as good as one weighing twelve hundred, and the extra three hundred pounds will cost not far from forty dollars extra. In those parts of the country where hay and meal are cheaper than here, horse keeping will of course be less.

For the cost of keeping in the country we know one gentleman owning a span weighing 1,000 pounds each, who estimates the weekly cost at three dollars. Another, with horses weighing 1,100 pounds, estimates the cost at three dollars forty cents per week. Another with a pair weighing 1,250 pounds each, at the same weekly cost. Another, with horses weighing 1,000 pounds each, estimates the cost of keeping at three dollars forty six cents a week. This last would be twenty four cents and a fraction a day, a medium between the extreme cases in this City. These cases are taken from Eastern Massachusetts where hay and grain are rather higher than with us. The estimates are for horses worked every day at severe labor. Where horses stand in the stable and are worked but a part of the time, or where they run in the pasture in Summer, the expense will be considerably less. We think it will be found in actually experimenting, that the expense of keeping a horse varies from one to three dollars a week. In all the cases quoted, the food was given by measure, and the fact that the horse kept in good condition, was proof that he had enough. Where a horse has all he will eat, as is often the case, he will consume much more than is necessary to keep him in good flesh. You may safely add a third to the expense of keeping, where a horse is fed in this way. In the omnibus business the average life of a horse is three and a half years; on the railroads it is four years. In the country the average term of service must be at least three times as long. Horses are frequently found twenty years old, and in rare cases thirty years and upward. This short term of life in the City has to be added to the expense of keeping a horse; the longer term in the country makes it cheaper there. One hundred and fifty dollars invested in a horse here, is sunk in four years. There it lasts twelve. EQUUS.

[We acknowledge the receipt of several reports on the cost of keeping horses, giving facts and figures; which will be soon published.]

Value of Dead Animals for Manure.

It is no uncommon occurrence for the farmer, at this season of the year, to have "spare meat" upon his hands. He undertakes to winter more stock than he can carry through in good condition without buying hay or grain, and he does not see the economy of buying food. Some of the stock, unreasonable beings that they are, see the economy of dying, and do it—without consulting the owner. Here a sheep caves in under the wall, or a cow dies in the pangs of labor, from sheer want of strength to bring forth. Here is a dead lamb, ornamenting the fork of an apple tree; there an old horse falls at the manger.

It would be stating the case rather strongly to say that a dead sheep was worth as much for manure as for mutton, that is to say, five cents a pound. The facts might not warrant the statement which we have seen in an agricultural work, that a dead horse well composted was worth twenty loads of manure, that is to say, twenty dollars, though this would come nearer to the mark. Allowing the horse to weigh 1,000 pounds, and the muck and labor to be worth $10. This would make the carcass worth $10, at one cent a pound. It might not be advisable for a farmer to buy carcasses at this rate, while it would pay largely to save every thing of the kind upon his farm, or within his reach.

According to the experiments of Messrs. Payen and Boussingault, three pounds of muscular flesh contain the same amount of nitrogen as a hundred pounds of farm-yard manure. Soluble blood, and salted cod, had the same value. Two pounds of cow's hair, two pounds of woolen rags, two pounds of feathers, two of horn-rasp-ings, were each equal to a hundred pounds of farm-yard dung. They are among the most valuable substances used for manure, according to these experiments. If a half cord of farm-yard manure, weighing about a ton, is worth a dollar, then hair, wool, feathers, etc., would be worth about two cents and a half a pound, and the flesh about a cent and a half, at the same rate.

It is not necessary to attain results entirely accurate to show the economy of saving all these wastes. Above ground they are a nuisance, and a source of disease. Buried, they are lost. But in the muck heap, and composted, they are a source of profit, and pay largely for the labor. We want the crows to prey on grubs and insects, and not on dead animals. We can put these to a better use. Every pound of flesh, rightly used, gives a peck of potatoes. Let them be saved. JONATHAN.

Jonathan's hints are good, but he does not tell what to do with the carcass after we have it. Here is a plan we learned from Mr. Geo. H. Goodwin, of Hartford County, Conn.: The horse is bought as cheap as possible; of course better alive than dead, as a general thing, if he can walk. Four loads of muck or sods are placed in a convenient out-of-the-way place, yet within sight, so that dogs can be watched, and if they manifest too great a regard for the old horse, a well-directed bullet may introduce them to a still closer companionship. Then the horse is taken upon the heap, killed, and the skin removed, which more than pays for the job. Without further ceremony five or six loads of muck and soil are thrown over the carcass, and it is left six months or a year, according to the season, a certain amount of warm weather being necessary, and it not being agreeable to overhaul the heap in the heat of Summer. Then fork it over, throwing out the bones, which will then be well freed from flesh, sprinkle over the heap a peck or two of plaster, and add perhaps a little fresh muck or soil upon the surface; let it lie a month, then fork it over again, and it is fit for use and an excellent manure—worth more than an equal bulk of good barn-yard manure. The bones thrown into another heap, or into the stable manure, to be thrown out again when it is forked over, soon become so rotten that they may be pounded up and used with the manure, or by themselves.

Tim Bunker on the "Horn-Ail."

"What is the matter with your cow, Mr. Frink," said Seth Twiggs, as he leaned his elbow on the barn-yard bars, and looked benevolently at a very spare and hirsute animal, that Jake was milking.

"Can't tell exactly," said Jake, "Guess she's got the horn-ail, or some sich thing."

"I thought the trouble seemed to be in her legs, when she come by my house last night. She walked kind o' totlish," said Seth, knocking the ashes out of his pipe.

"Wa'll that might be. Horn distemper generally affects 'em all over. Had Tucker up here to doctor her last night; he said it was horn-ail."

"What did he give her?"

"He gin her a slice of salt-pork, split her tail, put in salt and pepper, and bored her horns."

"Rather guess there was some squirming."

"Yes, it took three men and all the ropes in the barn to hold the old keow."

"Don't you think horn-ail hurts the milk?" inquired Seth hesitatingly as he relighted his pipe.

"Wa'll as to that, I can't say. It's all the keow we've got, as gives milk, and shouldn't think any trouble in the horns would strike clean threw the beast. Milk is milk, I take it, no matter where it comes from. I never could see any difference in the taste."

"I rather guess milk wont be milk out of that animal much longer," said Seth ominously, and blowing a puff of smoke as blue as his prophecy.

"You don't think she's going to die do you?" asked Jake solemnly.

"The crows have already held a counsel on that animal. Tucker told me so last night."

"The scoundrel! He told me he would warrant her to get well, if I'd give him a dollar for his doctoring."

Two days after the above conversation I was called in to administer upon the carcass of said animal. Jake said he had human feelings, and he could not skin a cow he had milked, and he did not even want to put her in a muck heap. I gave my neighbor due credit for the feelings of tenderness which the death of his cow seemed to call forth. But I could not help thinking that a little more of that tenderness manifested to the animal while living, would have been much more wisely bestowed.

To tell the plain truth, the animal died of starvation, just as many cows die every year in this land of steady habits and Christian civilization. I noticed the cow last Summer, and told Jake he would certainly lose her if he did not give her a better pasture. But he would keep her with his young cattle in the old cow-pasture that has been grazed to my certain knowledge for fifty years, and probably for a hundred, without plowing or manuring except the droppings of the pastured animals, and these were yarded at night. He kept six animals where there was not grass enough for three. They came out of the Winter poor and thin, and this cow having the drain of milk upon her system grew thinner through the Summer. The winter diet of corn buts, bog meadow grass, and salt marsh hay cut short the work of starvation, and fulfilled Tucker's prophecy.

They have a great variety of names for this process of torture in Connecticut, and I suppose in other parts of the country. Sometimes it is horn-ail, or worm in the tail; again it is slink fever, or murrain, black leg, or black tongue, cattle disease, or pleuro pneumonia. It would not do for an intelligent civilized man to see and believe that he starved his cattle to death. Conscience might trouble him, and possibly some of his neighbors might have him before the courts under the statute which prohibits cruelty to brutes. If I were called to judge in such a case it would certainly go hard with the offender. It certainly inflicts more pain upon a brute to starve, than to beat it. The whip upon ribs well lined with fat is a sharp torture soon over. But to keep a cow at the stack-yard through the cold stormy nights of Winter, to give her poor food and not half enough of that is a lingering torment, more cruel than that which the savage inflicts upon his victim bound to the stake. The poor beast can only speak through the hollow ribs, and the bristling hair, and these signs of woe are usually attributed to disease rather than to a lean manger.

This is an evil that legislation will not reach, and I suppose nothing but public opinion will set it right, and that probably not in our day. It would seem that there was no need of losing neat stock under ordinary circumstances. I have kept cows for over forty years, and they have all died by the knife, proving as useful and ornamental in their deaths as in their lives. The starving of animals is so unprofitable, that there is no apology for it. A half starved cow hardly pays her keeping. A well fed one pays a handsome profit.

My recipe for the horn-ail is, one good warm stable well ventilated and well littered, one bushel of carrots or sugar beets daily, hay and water ad libitum, one card or curry-comb, and gentle treatment. I have never known this dose to fail of preventing the disease.

Hookertown, Apr. 10th, 1862. } Yours to command, TIMOTHY BUNKER, Esq.

The Best Team for the Farm.

We have three kinds in extensive and very general use in different parts of the country: the mule on the cotton and sugar plantations; horses on the prairies and smooth farms of the western and middle States; and oxen in New-England and on rough uneven farms generally in the Northern States.

So far as the plantation team is concerned, there is little room to doubt that the mule is the best animal. He is more hardy, and will bare that abuse which is inseparable from the forced labor of the South, better than the ox or the horse. Neat stock are short lived in the Gulf States, perhaps quite as much from scant forage as from the peculiarities of the climate. Tradition says that "a mule is never known to die upon the plantation," which is probably a strong way of stating their longevity. They endure the heat as well as the negroes, and are well adapted to slave drivers. It is a question if more mules might not be profitably worked upon northern farms. Most of the mules are raised in Kentucky, and in the States further north, and possibly if there were not so great a demand for them on the plantation they would be more frequently seen upon the farm. Pride probably has as much to do as profit with the general disuse of the mule at the north. He does not look

as well as the horse, has less sagacity and speed, and is thought to be more vicious. It may be said in favor of mules that they thrive on much plainer food, and are strong and swift enough for most farm purposes. They are excellent draft animals. Most of the carting in New Orleans and other southern cities is done by them.

Much has been said upon the comparative merits of the horse and ox, for the northern farm, and each has its strong advocates. Neither can be shown to be best for all kinds of land. In behalf of the ox it is said, that he is slower than the horse, and so is better adapted to carting over very rough roads and woodlands and to plowing land full of stones and roots. Oxen can be used where horses would tear harnesses and carts all to pieces. The ox also is available for beef, when he has served faithfully in the yoke for eight or ten years. A pair of heavy working cattle, in good condition, are frequently worth quite as much for the butcher as for the farmer. The horse in old age is only good to "trade off," or in case of death, for the crows or the manure heap. The slow motion of the ox which seems to be the strongest argument in his favor, must be against him with all progressive farmers. Rough fields ought to be cleared of rocks and stumps so as to make room for the plow, the mowing machine and the reaper. With a farm in the condition in which it can be most economically cultivated, a horse team is the most profitable. Their quickness of motion is a very great advantage, and in the course of the year shows many dollars gain in the saving of time. On the road a horse team travels nearly twice as fast as an ox team. In plowing, a pair of horses will plow as much in two days as a yoke of cattle of the same weight will in three days. The horses also will stand the heat much better.

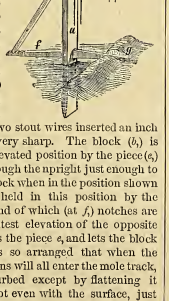
Contrary to the general impression, too, we believe that the horse is more cheaply kept than the ox. Where there is occasion to keep the animals in the stable and to feed with hay and grain, as is generally the case where the teams are kept constantly at work, the horse is the less expensive animal. The experiments to which we have access go to show this. In plowing and tillage the work is much better done by the horse. In turning the furrow over rapidly the soil is broken up more finely and lies lighter, making a fine seed bed. All the tillage necessary for corn and potatoes in clean land can be performed with the horse. He is altogether the nobler animal, and exerts a refining influence upon his lord and master.

Mule Raising.

Whatever may be said of the esthetics of mule raising, there is but one side to be taken in regard to the profitableness of it if wisely managed. Let us look at a few facts. Mules are hardier, cost less to keep than horses, are sold unbroken, and are ready for market the Fall after they are 2 years old. They are driven to market in droves and sold like cattle; that is, the buyer has no recourse, as in case of horses, if he finds the mule lame, foundered, balky, or 'dead—unless gross deception be practiced, and the price paid is clearly money obtained on false pretences. They are always marketable, having a definite value, and a ready sale, as much so as neat cattle or sheep, and even halt and maimed animals bring a proportionate price. It is not an uncommon thing to hear a man say when remonstrated with for working a crippled mule—"It will out-work any horse I have got." Allow that at two years old, a mule and a colt of like age have cost the breeder the same sum. The mule is ready for market, or nearly so and he is worth 20 to 25 per cent. more than the horse.—Price of mules will average fully 20 per cent. higher than horses. At a year and-a-half old the mule may be put to light work without injury and rather to advantage, and from that time on may earn his own living at least. The horse is salable at 5 years old, but not then unless he is broken. He can not be put to work of any kind much before four years old; and during all this time his breeder has to run the risk of accidents, sickness, bad breaking, and luck in marketing. There are several other important considerations. Many a mare which brings inferior colts will produce mules of very salable quality, and yet the finer the mare, other things being equal, the better mules she foals. Many Kentucky and Tennessee farmers have long used *thorough bred* mares for mule breeding, and their mule stock is exceedingly fine. The excellence of the Jack is not less essential to marked success, though as already stated, any and every mule finds his market and that, too, without "jockying." The Superintendent of the Sixth Avenue Railroad in this City states that in employing mule labor there is a saving of 3 per cent. in casualties, 12½ per cent. in keeping, and 25 per cent. in shoeing. Still, we believe, for some cause the trial of mules upon this and other city railroads, resulted unfavorably to their continued use. Mules are adapted to work on level ground, for they can not hold back well, and except as saddle beasts will never be much used in hilly countries.

A First-rate Mole Trap.

We have received several mole traps, and models of traps, for catching these vermin, among all of which the one represented below appears the most simple and practical. An upright piece (a,) 1 x 3 inches, and 2½ to 3 feet long, sharpened so as to be driven firmly into the ground, sustains a heavy oak block (b,) attached to it by two wooden clamps (c,) which allow it to slide with great freedom up and down. Nailed on the block is a cross-piece (d,) 10 inches long and two wide, which has at each end two stout wires inserted an inch apart and made very sharp. The block (b,) is sustained in an elevated position by the piece (e,) which passes through the upright just enough to catch upon the block when in the position shown in the cut. It is held in this position by the piece f g, in one end of which (at f,) notches are cut, and the slightest elevation of the opposite end (g,) disengages the piece e, and lets the block fall. The trap is so arranged that when the block drops the pins will all enter the mole track, which is undisturbed except by flattening it down with the foot even with the surface, just at the point where the end g, of the piece f g, will come. The block is lowered once or twice so as to be sure that the pins will penetrate the soil without difficulty. The trap is then set, and



g just touches the ground where it is trodden down over the mole track. The block must have a fall of 12 to 14 inches. The pieces e, and f g, are each about 15 inches long, and made very light. The slightest lifting at g, will throw e out of the notch in f, and let the block fall. The mole approaching from either direction, raises the ground before him, springs the trap, and the points will most surely pierce his body. Experiments have proved that the best distance apart for the pairs of wires, is 9 inches, letting them enter the ground about 4½ inches from the trip g. The block b is a piece of rough scantling, with the piece c, nailed on. The whole is easily and quickly made. For this plan we are indebted to Mr. W. Norton of Mercer Co., N. J., who has used it with entire success for several years.

A few Hints about Plowing.

For some time past we have been waiting to give in the *Agriculturist*, promised essays on plows and plowing; but those best able to discuss the subject, scientifically as well as practically, are still too busy otherwise, to make the requisite drawings to illustrate the principles, and to go into a thorough treatment of the subject. (We have plowed a good deal of land, and think we could teach some of our readers could we get them with us into the field and teach by example.) While waiting for what we desire to get from others, let us offer a hint or two.

The object of plowing is to break up, to pulverize the soil—*to make it as fine as possible.* That plow is not always the best which will turn over the neatest furrow. To merely invert the surface layer, or shift the position of the soil in masses, or in furrow slices, with the least expenditure of team power, is not the only end to be sought for. Some of the old-fashioned moldboards will often stir the soil better than the newer patterns that show the least strain upon the dynamometer. For sod-land, and where the surface is not pretty clean, it is generally desirable, however, to turn the furrow neatly over. The grass, weeds, etc., being well buried, the pulverizing of the surface can be done with the harrow or cultivator.

Clay soils, or heavy loams, should never be plowed when wet enough to pack, mortar like: the great desideratum is to loosen the soil for the admission of air and warmth. Light sandy soils, on the contrary, may sometimes be benefitted by plowing them when wet.

Very deep plowing is not always advisable, except by subsoiling. The truth is, nearly all soils are poisonous to plants until after they are exposed to the action of air and frost. Many a man—once a skim-plower running the share but three or four inches deep—has got it into his head that the deep-plowing men are right. He goes home, doubles his team, and at once puts down the plow twice as deep as ever it went before. The consequence is, he turns up a mass of *raw* material, and the next crop is nearly or quite a failure. He, and his neighbors, at once eschew all the new-fangled notions, sink back into the old routine, and there is an end to all further attempt at improvements in that neighborhood. But had there been an inch or so of the raw soil turned up for each successive crop, and the tilth been gradually deepened year by year, the evil consequences would have been averted, and in a brief period, five or six years—the plow, the air, and the frost working together—the most happy results would have followed. The roots of the grass, of the corn, of the wheat

and of other crops would have found a lodgement below the temporary surface influence of parching suns, and find access to unfailing supplies of moisture and nutriment.

Fall plowing, to turn up the lower soil, and expose it to freezing and air during Winter, acts like a charm on Spring sowings and plantings.

But by far the best means of deepening a soil, is the use of *a subsoil plow.* This implement is very like a common plow, with the upper and main part of the mold-board cut off; or rather it has a low, narrow, lifting flange in place of the mold-board, so set that it lifts and breaks in pieces the soil. It is run in the bottom of the furrow, following the common plow, two teams being required for the operation. It breaks up and pulverizes the subsoil without turning it up to the surface. This admits air, and after a year or two the subsoil is fitted for being brought to the surface. *Such an operation pays on any soil.* It begins to pay on the first crop, and continues to return a very large yearly interest on the cost.

Mr. Mapes strongly recommends a subsoil plow which he claims to have invented or designed. It is called the "lifting" or "mole" plow. To us this seems the poorest kind of an implement for a subsoil plow. It is like a thin double wedge, with a shaft running up to the beam, and its principal effect is to lift up the soil a little and let it partly fall back, without pulverizing it more than the few cracks made. The common subsoil plow, which thoroughly disturbs, breaks up, and pulverizes the subsoil, is doubtless by far the better implement.

Pumpkins Alone and Among Corn.

Doubtless thousands of the readers of the *Agriculturist* regard the corn field as the only place for raising pumpkins. But, however little the harm that pumpkins do the corn—and we believe that in good seasons they produce a quantity of food which much more than counterbalances the evil which they may do—they will yield a much larger and finer product if planted by themselves. Putting the hills 8 feet apart, two or three good shovelfuls of well rotted manure being dropped on the surface and covered by a little earth, the pumpkins will luxuriate in unobstructed sunshine and upon the fat of the land: and when Autumn strips away the leafy covering under which they hide, a golden harvest will be disclosed which will do one's heart good. Low growing, small stalked varieties of corn do not essentially interfere with the ripening of good crops of pumpkins. But if planted with corn they should in no wise interfere with the thorough culture of the corn. A good plan is to drop seed in every other hill, in alternate rows, and it is very important to secure good seed. The medium sized, round dark orange colored, fine grained varieties are best, and usually the earliest, most prolific, and the best keepers. The cheese pumpkin is preferable for family use or for market.

Field Beans with Corn.

One of the crops used to fill out corn, when it grows scantily, or has altogether failed in hills or spots, is the white bush bean. There is wisdom in the selection. The leguminous and cereal crops are considered so essentially dissimilar in their drafts upon the soil, that they are adapted to follow each other in any rotation. So far as we are aware, experience has not yet discovered that corn suffers essentially, if at all, for having a large crop of beans grown at the same time upon the soil. A heavier draft is, of course, made upon the *soil* if a large crop, be taken off. It is a common practice in some good farming communities, to drop a few beans on the south side of every corn hill having less than three stalks. Another method is the following: The corn being in hills equally distant, in rows running both ways, at the second hoeing, after plowing or running the weeder both ways, plant beans between the hills in the rows running one way. Others plant similarly at the same time that the corn is planted.

Beans cultivated by themselves are a very profitable crop, not exhausting to the soil, and an admirable food for sheep. They uniformly bring a remunerative price, and are sometimes very high and in great demand. They do best on good corn land, not richly manured, in rows 2½ feet apart, kept well weeded and hoed.

Tobacco Cultivation—No. III.

The farmer who cultivates this crop, if he would succeed, must stand ready at all times to neglect every thing else for it. It must have the choice manure of the farm, and when the time comes to transplant, the tobacco must be set, if the weather favors, no matter what stands in the way; then the plants killed by grubs, or those that fall from other causes, must be renewed immediately, and the regular tillage of the soil, and weeding, must suffer no interruption. Soon the worms begin to appear, and as the plants grow they multiply; they find more hiding places, and doubtless more escape the eye of the cultivator. Neglect of them is fatal to success, and the tattered, worm-eaten leaves show a single day's neglect. As the plant approaches maturity, the topping, suckering, and the never ceasing worming, demand of the cultivator unceasing watchfulness and activity; and finally, when the plant is nearly ready to be cut, and day after day adds to its value, up to the very latest time before a frost would ruin it, all hands must be held ready to leave every thing else to harvest the tobacco. The culture is disagreeable work after the plants attain any considerable size, and at all times requires the eye if not the hand of the master.

The tobacco cultivator is subject to one very great temptation, to which if he yield, he permanently damages his farm. The worn-out tobacco lands of Virginia, Maryland, and Kentucky testify to the ruin sure to follow in the wake of the shiftless culture of the weed. Throughout those tobacco-growing regions with which we are acquainted, as a general rule, beside the fine looking tobacco field, stands the half-starved corn. The hill-sides wave with rye, or lie bare in fallows, waiting the revolving cycle when they will again be able to bear a crop of rye or buckwheat. Three-quarters of all the manure made on the farm, and very often all of it, is applied to the tobacco-field, and year after year it is planted upon the self-same plot, and is depended upon as the only source of ready money. As a system of transferring the wealth of the land to the banks, railroad and insurance companies, this works well. The errors of such a system are so patent that it is a wonder any one follows it, but the temptation is great.

When the tobacco crop takes its place in any systematic *rotation*, following some hoed crop, it may be of very great utility and profit to the farmer, and gradually he will be able to increase the land cultivated, and still have manure enough, and not rob the rest of the farm either. Under all circumstances then, we are prompted to ask each tobacco raiser: May you not cultivate other crops with less risk and equal profit, if you devote the same labor and care to them? Lima beans, peas first and cabbages to follow, early potatoes followed by cabbages, and other crops which might be named, are worthy of careful consideration.

But if tobacco is to be raised, by all means do it thoroughly. Early in May, or before, manure and plow deeply, and if any portion of the subsoil is brought up by this operation, apply and work in to the surface a good dressing of wood ashes. The plant demands and withdraws from the soil a large proportion of potash; and besides, this is one of the very best ameliorators of soil which has not been exposed to the action of the air. The manures desirable are: barn yard manure, rich composts of any kind, bones in any form, home-made poudrette, hog manure, etc. Guano is not desirable, except perhaps in very small quantities, as it affects the color of the ash, and perhaps the color of the cured leaf unfavorably. A light dressing of salt or lime, or of both, on the surface is productive of good results, but avoid heavy applications.

The ground thus well prepared as for a corn or root crop, but richer, remains until after the 10th of June when we may expect settled hot weather soon to come. It is then harrowed thoroughly, or lightly plowed, and harrowed, and rolled, marked out in rows three or three and-a-half feet apart, and the first cloudy or rainy day after the 15th of June, the plants are set three feet apart, or even nearer in the rows.

It is the practice of some tobacco cultivators, and on some land it is desirable, to plow in or harrow in about a third part of the manure when the land is worked in June; others set out the plants, manuring "in the hill" with poudrette, superphosphate, etc.; and others make no further addition of manure after the ground is once well prepared as we have described.

Young plants in the seed bed may be brought forward very much by occasional waterings at evening, with weak guano water or other liquid manure.

Hints on Corn Planting.

"One swallow don't make it Summer," and a few pleasant days do not make it corn planting time. Early planted corn is very apt to fall, to rot in the ground, to become the prey of birds, squirrels and mice, to be cut by the grubs, or to be checked or killed by frosts. Corn needs the hot, moist weather of the last of May, or first of June, to bring it forward rapidly and vigorously. The rhyme of some old almanac has grown into an adage,

"Sée your corn field in May, you'll turn sighing away
But see it in June, and you'll sing a tune."

Or another version of the same idea is:

"Your corn in May will make you pray,
When you see it in June, then you'll sing a tune."

The doctrine often stated that corn makes roots in May, is an error, so far as it conveys the idea that corn will make roots faster or better in cold rainy weather than in warm; but correct if it only inculcates the desirableness of planting so that the corn shall be just breaking through the ground and ready to take advantage of the first hot weather. Corn planted early in May, and struggling for life during the first three weeks of its existence, will be completely outstripped by that which is planted two weeks later. The late planted will be evener, larger, and more productive; and we presume also, just

as early; although in regard to this latter point it is true that an inferior plant will often ripen what seed it bears earlier than one which takes a better hold of the soil, and remains green and growing a longer time. Corn planted north of lat. 41° before the middle of May ought not to be much soaked. There is too much danger of a cold rain setting in which will cause the seed to rot in the ground. But planted during or after the third week in May, it is commonly safe enough to soak it. If it be soaked in water containing blue vitriol, seeds of smut will be destroyed. A good plan is to use common pine tar, (not coal tar,) dissolving a quart of tar to a gallon of warm water, and stirring the corn in the fluid. Then dry it with plaster; a small quantity of lime may well be added to the plaster, to destroy any smut. This preparation is not only a fertilizer, but renders the seed distasteful to crows, blackbirds, squirrels, etc.

Corn planting implements are very desirable, and labor-saving. Billing's planter is one of the oldest and best. It plants corn in hills or drills at distances varying within certain limits, drops a fertilizer in the hill if that be desired, and at the same time plants beans between the hills and without manure, if it be arranged for this purpose. There are doubtless other corn planters, perhaps equally good or better, but with this we are more familiar. It is seldom worth while to plant field corn before the 15th of May, north of this latitude, and at the far north it is seldom possible. We advise planting all varieties of *flint* corn (that is the white, and yellow, or red 8 or 10 rowed varieties which are the common field corn of the northeastern States) in drills so that when finally thinned out, it shall average about one stalk to 10 inches—the drills 3 to 3½ feet or more apart, according to the kind of corn. Manure applied in the hills or drills is often of marked benefit, and very small quantities are often quite as effective as larger. Even soaking the seed in water containing nitre, or nitrate of soda, has a great effect. Stall manure applied on the surface, and harrowed in, is most available to the corn crop, whether the soil be deep or shallow, rich or poor, hard or mellow. On very sandy land, lightly plowing it in, is better than harrowing.

Sorghum Syrup Produced at the far North.

Our call for information in regard to the culture of the Chinese sugar cane above latitude 44° is responded to by a subscriber to the *Agriculturist*, in southern Minnesota, whose experience is instructive. He writes: "I have experimented with sorghum for three seasons. The first year I made eighteen gallons of miserably poor molasses from one fourth of an acre of cane so nearly ripe that about one seed in twenty would grow. The second year I made fifty gallons, good, bad, and indifferent, from half an acre of perfectly green canes, not a seed colored and many seed heads were not in sight. Last year I made of entirely unripe canes, beautiful molasses, needing no 'refining,' at the rate of one hundred gallons per acre. My practice is, to keep everything clean; to grind the canes as soon as cut, and boil the juice speedily, in a shallow vessel; to reject all purifiers, especially alkalies; to remove the green coloring matter which gives the unpleasant flavor, by frequent strainings and thorough skimming. Having ascertained that with the rudest kind of apparatus, *prime* molasses can be made from unripe canes, I intend next season to plant several acres, and procure better apparatus for manufacturing the syrup. At half the present prices of 'sweetening,' it is the most profitable business to which we can apply our industry, here in Southern Minnesota." WM. M. BUNNELL.

Timothy Mowing Lands.

Timothy is a poor pasture grass. That every body knows. The close browsing herd will soon rid a field of it, except in the hedge rows where they can not crop close. The reason of this is not because the root is somewhat bulbous, for we can not understand why that should affect it one way or another, but the fact is that the dormant buds at the crown of the root or the base of the stem need the influence of some foliage to cause them to start. The root alone is very likely to be unable to produce another vigorous shoot, and so it dies, or is greatly injured. Thus it is the very worst policy to let cattle of any kind closely feed down Timothy meadows at any time of the year, and particularly in Spring where the full vigor of the root should go to the unimpeded development of the plant. Timothy appears to receive more of a shock from cutting than almost any other of our common grasses, and almost uniformly makes a poor aftermath. A dressing of manure upon Timothy mowings immediately after haying, seems to counteract this evil. Not only may a good aftermath of Timothy be secured, but all other grasses, so far as we know, are more benefitted by manuring at this season than at any other. *

Gleaning in Foreign Fields.

BY ELIHU BURRITT.

Utilizing London Sewerage.—One of the greatest works of modern times is proposed for forcing London to give back to the lands that feed it, some compensation in the shape of fertilizing material. The amount of sewerage it has hitherto poured into the Thames from its subterranean arteries, is estimated at 263,667,090 tuns per annum. Its value, in the diluted state, is estimated at 4 cts. per tun, which would make the whole annual volume amount to over $10,000,000. It is proposed to force this up into elevated reservoirs, at some distance from the city, on each side of the river; each reservoir to be 15 feet deep, and cover a space of from 10 to 12 acres. From these it is to be distributed by a system like that of the Croton Waterworks. Any farmer who wishes to turn a fertilizing stream upon his land, will be furnished with a supply pipe, and a meter, to register the amount he draws from the main, for which he is to pay as for gas or Croton Water, at a certain stipulated price. Should this experiment succeed, who knows but that it may cheapen the price of guano in America, by lessening the English demand for that article.

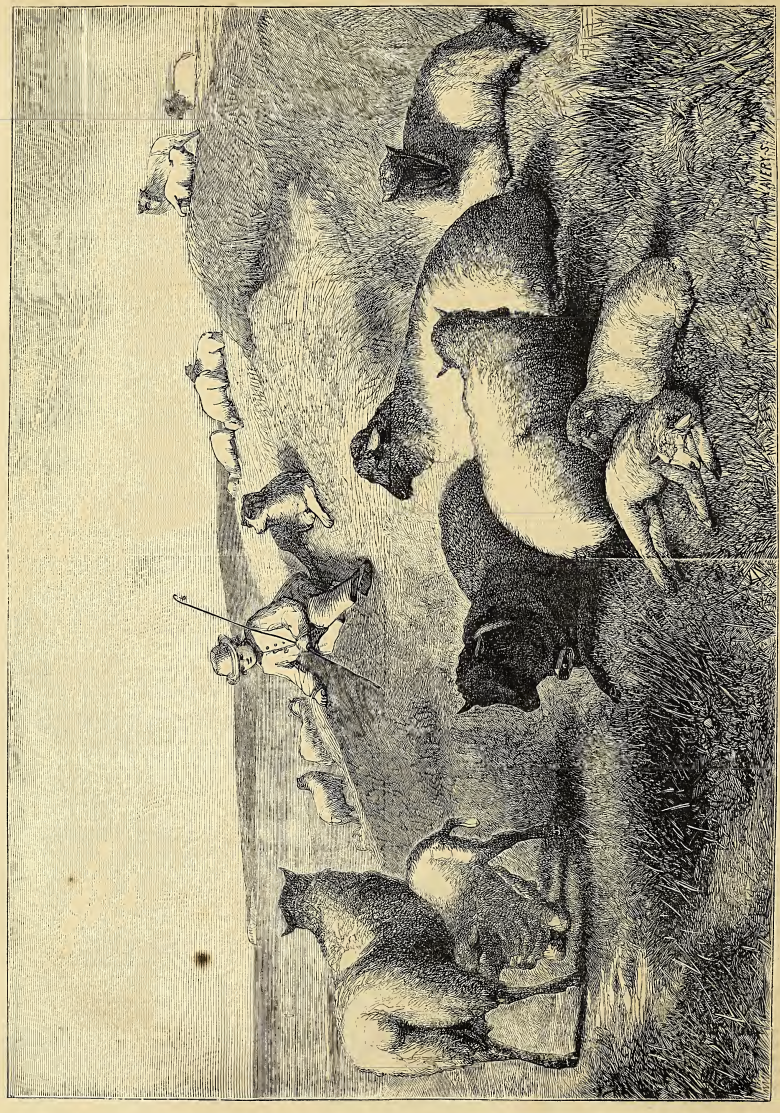
Lecture on Pigs.—*(Illustrated by Specimens.)*—Mr. Stevens, the Prince of the Pig Ring in England, who has taken the highest prizes at the National Exhibitions, recently delivered a lecture on the subject before the Farmers' Club, at Framingham, Suffolk Co. He made a grand *entree* into the town with a procession of ornamental cars, containing living specimens of the White Suffolk, his favorite breed. These were introduced into the hall, and behaved with much decorum, and showed good breeding as well as breed. Specimens of the feeding troughs, and of the pens, were also exhibited. In his address he advised making the floors of asphalte, and keeping the pigs warm and dry, washing and scrubbing them frequently, feeding them with warm food, etc. To prevent the sows crushing the pigs by lying down on them, he placed a railing around the inside of the pen, from 9 to 12 inches high, and about a foot from the wall, so that the pigs could pass between the sow and the wall without any danger of being hurt. To prevent the sow eating her pigs, he had their side teeth nipped out, when they were three or four days old, in case they projected. This put a stop to their biting the sow, and being bitten in return. Mr. Stevens thought he had reached the extreme point of progress, in producing pigs weighing 200 lbs., when five months old. Many an American farmer can tell a larger story than that. Why would it not be a good and proper thing to challenge Uncle John Bull to meet Brother Jonathan in the lists of cattle, sheep, and swine next Christmas? We doubt if he could turn out a bullock in the Three Kingdoms that would outweigh John Sanderson's ox. (And it is a question if we can next Christmas.—ED.)

Agricultural Machinery.—Those Americans who visited the Great Exhibition in London in 1851, will remember how meagre, at first sight, was the show of American art and genius, as compared with the contributions of some other countries. They well remember the satires of *Punch*, and the ponderous wit of the London Times, at our expense. They will remember with what supercilious distrust the American Mowing Machine was peered at, even by English farmers; how backward they were even to allow it to be tried on their fields. But, before that Crystal Palace was taken down, the London Times had the grace to admit, that if nothing else but the American Mowing Machine had been brought to the notice of Europe in that grand edifice, its expense would have been well repaid. In 1859, it is stated, that 4,000 reaping machines were at work during harvest, in England, capable of cutting more in a day than 40,000 able-bodied laborers.

Curious Manurial Estimates.—Professors Hembstadt and Schubler recently brought out an interesting table, showing the comparative virtues of different fertilizers, which the farmers might work at with profit. It is assumed that ordinary land without manure will produce a crop of grain equal to 3 times the seed sown; manured with herbage, grass leaves, etc., 5 times; cow dung, 7; pigeon's dung, 9; horse dung, 10; sheep's dung, 12; human urine, 12; human manure or bullock's blood, 14. The last, consequently, is the best fertilizer in the world. It has been estimated that a single individual produces 500 lbs. of urine per annum, which Prof. Johnston shows is worth $50 per tun. A village of 1000 inhabitants would consequently produce 250 tuns in a year, which would be worth, at this rate, more than $10,000. The population of New-York and Brooklyn would furnish annually for country farms $10,000,000 worth of this fertilizing material, *if* it could all be saved for that purpose.

Bee Culture.—Austria would seem, from authentic accounts, to be ahead of all other countries in bee-culture. The annual production, in honey and wax, is valued at $15,000,000. Hungary leads all the other departments of the empire, producing 90,000 quintals (100 lb.) of honey annually; Gelicia comes next, with 80,000 quintals; Transylvania, 50,000; while Upper Austria yields only 1,800. The total number of bee-hives is put at 2,733,000; averaging 270 to the square mile. If there were as many cows to the square mile, truly Austria might be regarded a land flowing with milk and honey.

Winter Irrigation in Italy.—This is an operation of great importance to Italian farmers. The right to water their meadows begins on the 8th of September, and ends on the 25th of March. The constant passage of the water over the roots of the grass stimulates the growth, but it also carries off a considerable portion of surface soil, rendering it necessary to make up this exhaustion by manuring the meadows twice a year. Five crops of grass are generally obtained on them in a year. To prepare them costs from $50 to $60 per acre, and the annual produce gives a profit of about $30. Others, near Milan, yield twice this quantity, as they are cut in November, January, March, and April, for stall feeding; and in June, July, and August, give three crops of hay, with abundant pasturage for September. They thus give seven crops a year, and the annual yield is immense.



SHEEP TENDING.—From a Painting by H. Brittan Wills, London.—*Engraved for the American Agriculturist.*

For the American Agriculturist.

Spare the Sprouts.

The grafts are set, and the sprouts are starting just below them—the effort of nature to restore the balance between top and roots, that has been destroyed by the grafting process. This balance is of much more importance than most people imagine. In a healthy tree it is always maintained. If important branches are lopped off, sprouts start immediately below to repair the loss. If small branches die, it is an indication of more wood than the roots can support.

In grafting trees of good size, ten years or more from the seed, not more than a third of the top should be taken off at once. The grafts will do much better if the lower limbs are left whole. Buds for new sprouts will start soon after the buds upon the cions, and there is a strong temptation to rub them off upon the supposition that more of the sap will be thrown into the graft. But this philosophy is wrong. Every leaf acts as a pump, and the sap drawn up, other things being equal, will be according to the number and vigor of the leaves. These sprouts should be left until the middle of the growing season at least, and then be removed gradually, leaving two or three sprouts in the case of the most vigorous trees to the second season. If the cions do not grow it is still more important that the sprouts should remain. JONATHAN.

How to Set Trees in an Orchard.

The common way is to set them in squares (fig. 1,) in the intersections of lines crossing the field, equally distant both ways. Thus each four contiguous trees form a square. The trees may be set at any desired distance apart—25, 30, and 35 feet are common distances. The advantage of this method is, that though the ground is not so perfectly occupied as it might be, still it is easier to plow between the rows. When it is desired to occupy the land still more thoroughly, or to place two sorts of trees upon it—one kind to be removed if necessary, as the others grow—dwarfs or other trees are set in the middle of each square, thus: This is confounded with the "*Quincunx*" system, (fig. 2,) in which the trees may be regarded as in *fives*, also: but not in squares. The Quincunx might with more propriety be called the Hexagonal system, for each tree is surrounded by six others at equal distance both from the center one, and each other. By this plan more trees can be set upon an acre than by the other, the distance between the trees being the same. The land can not be so conveniently plowed.

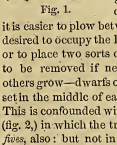


Fig. 1.

To lay out an orchard on the Quincunx system, the following rule may be given: Two distances of rows are required. The *first* is the required distance of the trees, 25, 30, 35, or 40 feet. The *second* is obtained by multiplying the first by 1.732, and cutting off the right hand three figures for decimals. *For example*, if the distance of the trees apart is to be 30 feet, then 30 multiplied by 1.732, gives 51.960 feet, or very nearly 52 feet, the distance of the rows the other way. Now lay off rows across the field one way 30 feet, and the other way, 52 feet, and plant trees at the intersections of the rows. Next draw a second set of rows, *each way*, just mid-way between the rows already planted. At each point where these *new* lines cross, put another tree, and you then have the trees all 30 feet distant from each other, but there are fully one-seventh more trees than if they had been set in rows 30 feet each way. The whole marking out may be done before beginning to plant. The above rule is a general one. If trees are desired 35 feet apart, 35 multiplied by 1.732, equals 60,620, or 60⅔ feet for the distance of the cross-rows. If the distance be 40 feet, the second or cross-rows will be about 69¼ feet, (69,280). The number 1.732 is very nearly the square root of 3, and is a "constant" for all distances of rows.

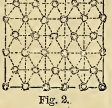

Fig. 2.

About Quinces.

Here is one of the old-fashioned fruits which deserves all that has ever been said in its praise. It is known botanically, as *Cydonia*, from the city Cydon, in Crete, where it seems to have first attracted attention. As a stock on which to graft the apple and pear, it has become quite serviceable, giving the fruit great precocity, increased size and improved flavor. Then, who does not know by experience that its own fruit when stewed, or mixed with apples in pies and tarts, makes a palatable dish? Says an old gardening author: "When apples are flat, and have lost their flavor, a quince or two, in a pie or pudding, adds a quickness to them. In medicine the expressed juice, repeatedly taken in small quantities, is cooling, astringent and stomachic." Quinces, says Columella, not only yield pleasure, but health." To make a first-rate apple pie, use one fourth quinces sliced with three fourths apples, and add a few thin slices of candied lemon-peel or citron, and more than a simple allusion to the delicious preserves, jellies, and marmalades made from the fruit in its purity, is simply an aggravation.

From the kitchen, let us now go to the garden. The quince may be propagated by cuttings or layers. The cuttings are prepared in the same way as for grapes, they should be set out in a deep, light, well-worked soil; if a little shaded, success will be the more certain. Let the rows be eighteen inches apart, and the plants six or eight inches apart in the row. Keep the ground well stirred during the Summer, and mulched in very dry weather. Layering is much practiced, and is a surer method than by cuttings. Shoots are bent down, slightly cut, and covered with earth. Another method is to earth up the mother plants in the Spring: shoots will spring up from the old stocks, with roots attached.

In setting out the young plants in their final position, place them ten feet apart, and give them the best culture. As the quince is often found will by the side of streams, it has been supposed by some that it needs a damp soil, and it is often set in the lowest and poorest part of the garden. A mistaken practice. Give it an open situation, a deep soil, and let the ground be surface manured every other year. The fruit will be abundant and large and fair, instead of scanty and knotty, as seen in its wild condition. Bushes well planted, and generously treated, will begin to bear fruit the third year, and will yield good crops for thirty years. First class specimens will bring two cents a piece in New-York market. Few crops are more profitable. The only pruning required is to cut out the old, and twisted or decaying branches. In addition to the manure, give an annual dressing of salt, just enough to whiten the surface.

There are only two varieties extensively cultivated, viz: the Apple or Orange quince, and the Pear-shaped. The first is the most popular, as it bears abundant, fair, orange colored fruit. The second is shaped like a pear, is dryer and firmer than the other. It does not become as tender, when cooked, as the other, but ripens a fortnight later, and keeps longer into the winter.

(PRIZE ARTICLE.)

The Apple Orchard.

BY ISAAC HICKS, NORTH HEMPSTEAD, N. Y.

It is generally admitted that, in all the older settled parts of the country, apple trees do not flourish as well as when the soil was new and not exhausted by repeated croppings, with a scanty return of manure to compensate the loss. Unless we fully determine to have an orchard that will remunerate both in profit and pleasure, and to which all other crops are a secondary consideration, we had better not undertake the business. The orchard is to be a *permanent* institution, at least for a life time. The best field on the farm is just the place for it to ensure the greatest results; and if it can be located near the house too, so as to be easy of access, all the better; for then it will receive more of the owner's attention and much labor will be spared in traveling to and fro for fruit—especially for Summer apples, which I recommend to be planted in the part of the orchard nearest to the house. A sheltered position from the northerly winds, with a forest, hedge, or hill in the rear, will often save part of the blossoms from frost and prevent the fruit from being blown off and lost. Generally a southern slope is best, and if nearly level and free from stones, it will be worked with greater ease. It is not to be expected that all these advantages can be secured by every one, but secure as many as you can. A medium soil that is not dry and sandy—parching up in the Summer drouths—nor too wet, in which water stands part of the year, but on which corn and potatoes flourish in perfection, is as near right as can be selected. And if we plant an orchard succeeding one of these hoed crops, the ground will be in the very best condition for transplanting. The finely worked soil is nicely adapted to filling in around the roots, and enables the rootlets to extract their food with ease, which they can not readily do if the earth is in a lumpy and hard condition. It is so important to have the ground in the best condition before planting, that it is better to defer the work until the ground is ready, than to plant in a stiff soil or with wheat, rye, barley, or oats on the ground. If the soil is light and sandy, make the holes twice the usual size and fill up with loam and sods if practicable, and spread a mulch for a distance of two or three feet around the tree to protect it from the scorching rays of the sun. On the contrary, if too wet, or if water stands on the ground, or if the subsoil is a heavy clay, it should be thoroughly drained before planting. If planted in a soil where each hole is like a miniature cistern, it is evident that the tree can not grow. It is recommended, in some wet soils, to place the tree on the surface and cover it up leaving it to grow on a small hillock. This is only admissible where soils can not be drained successfully, for the trees will not take good hold with their roots, and are more liable to be torn up by the winds. The practice of placing trees in little hollows, with the idea that they will catch the rain and be more moist, is erroneous, for repeated plowings in a few years fill up the holes, and the trees cease to grow from being set too deep in the earth. Apple trees send their lower roots deep down in the soil to absorb moisture from thence, and other roots rise near the sur-

face for air and food. Hence if these roots are too low in a wet, cold soil, the tree is robbed of part of the important elements of growth, it dwindles away and prematurely dies. Tenfold more trees are planted too deep than not deep enough, and if too deep at first they soon become more so, as most cultivators will plow more furrows towards the tree than away from it. Subsoiling before planting will be of advantage to almost all soils.

SELECTION AND PREPARATION OF TREES.

Every purchaser should, if practicable, make his own selection of trees to be planted, and not trust to the promiscuous collections of a tree peddler of whose knowledge or fidelity he has no assurance. Trees of the same kind vary much in the nursery rows; some are worth double as much as others for form and thriftiness, and if the purchaser attends to it himself he knows what he is getting. In purchasing largely at the leading nurseries a discount of ¼ to ½ can be saved from the prices asked by peddlers. Trees of healthy growth, with well formed heads, good roots, and true to name (a very important item), will, in after years, save much labor in pruning, give more satisfaction always, and amply repay the extra labor and expense in procuring them. Four or five years from bud or graft, if they have not been forced ahead too fast, or where it is no great object to save freight, from 7 to 8 feet in height is, I think, the proper size; but if they have to be conveyed a long distance, smaller and younger trees will be preferred. Before planting, cut out all superfluous branches and twigs, leaving three or four main branches to form a head. If the tree has fine roots, with a few main ones as braces, the top will require little or no cutting back. The top must be in proportion to the amount of roots. The buds of the previous year's growth give much larger leaves than older wood, we therefore cut but little off unless the roots are scanty. As the larger roots of trees are almost always cut off roughly by the spade in digging, their ends should be trimmed off smoothly before planting; a mass of small roots will spring from the end, much assisting the tree in its hold upon the ground. It should always be our special care to secure the most roots possible upon the trees we purchase, and to have them in the best order, for the after growth much depends upon this.

PLANTING.

There are two methods of planting, one the regular square in which the trees should be 30 feet apart, and the other called quincunx, or 5 to the square. The latter gives more trees to the acre; they will be 27 feet apart. Some varieties form much larger and wider spreading heads than others, and if the cultivator will take the pains to ascertain the manner of growth of the kinds of apple trees he plants, the distance between the trees may be varied somewhat to advantage. After the distance is staked, if the ground be mellow, mark it out with a plow each way, and plant the trees at the intersections. If in the quincunx form, mark 30 feet each way and plant at every other crossing of the plow. Having made our selection and marked out the ground, we proceed to dig the holes for their reception so that they may be planted with as little delay and exposure as possible. For although the apple is a very hardy tree, drying and exposure to cold winds will check their leafing out and their growth the first year. Dig the holes about 3 feet across, taking out the surface soil and keeping it separate from the subsoil. Two spades in depth is sufficient; then the sods, if there are any, and surface soil should be thrown in until the tree can be placed at the same depth it grew. Next throw in good friable surface soil carefully around the roots, placing them in the same position they originally grew, and gently shake the tree sidewise. A few minutes' attention to the proper placing the roots, working the earth between the roots with the fingers if necessary, will pay for the trouble. Lifting the tree up and down like churning is not a good practice, as the dirt falls in at the end of the roots, misplacing them in an arching manner. To insure a quick growth, the rootlets must have good food in the soil, and hence the necessity, whatever the surrounding soil may be, that good rich earth should be in contact with them. Well rotted manure or compost may be placed in the holes, but not in contact with the roots, and then covered with soil and firmly trod down. Two persons are needed to plant a tree properly, one to hold it and the other to fill in the dirt. No fresh or unfermented manure should be placed under or around the roots of the tree; always put it on the surface. As we need more surface soil than we dig out of the hole, it may be taken from near the heap of subsoil, and when the planting is done the subsoil is put into the hole made by its removal. The best time for transplanting is when the best attention can be given to it. If properly done there is little difference between Fall and Spring. Probably the tree is more likely to live if there should be a drouth the succeeding Summer, and its growth be greater, if planted in the Fall. But there is, in ordinary seasons, almost no risk of apple trees living unless grossly neglected. When trees have been brought from a long distance, it will be better to wet them previously, dipping them in water, or pouring water in the holes when planted. If the ground be kept mellow by frequent stirring with hoe, plow, or cultivator, no better mulch can be given the young tree through the season. There is nothing equal to frequently stirring the surface to enable a tree to withstand drouth. [If the root fibers are not touched or disturbed. ED.] But where this can not be done owing to the trees being planted in a grass sod, or among the cereal grain crops, a good mulch of anything that will prevent the moisture from evaporating will be of service. Hay, straw, cornstalks, old weeds, shavings, and leaves, are all good, and it is much better at all times to throw refuse rubbish around trees for a mulch than to burn it up, doing good to no one.

Trees will require more or less pruning until they are grown. We should go over them every year. Spring is the time when most persons have leisure, and if the growth of the tree is properly watched, few or no large branches need ever be removed. The head of the tree should be kept so open that a person can climb up and about without difficulty, and every year as the trees increase in size we may find small branches or shoots which need removing. While the trees are young no tool is needed but the pruning knife. But as they grow out of reach, a saw with the teeth reversed so as to cut with a down stroke and fixed on a long handle is the most convenient. There are many different tools for effecting this object for sale at the agricultural stores, but when one of these can not be procured, a substitute can be made by taking the handle from a common back-saw, the smaller the better, filing the teeth reversed, and fastening it to a pole or hay-fork handle. As to the time of pruning trees, some advise to cut when the knife is sharp. When the limbs are quite small, the best time to trim is whenever we perceive it to be needed. Large limbs heal over much better if removed very late in Spring or early in Summer, and if smoothed over with a knife, they will be covered with new bark in half the time. It is a matter of individual taste whether to trim high, so that the plow can always be run under the boughs, or low, drooping their branches to the ground. Both ways have their advocates and advantages. Many kinds of apple trees, like the Bellflower and Rhode-Island Greening, have such a tendency to droop, that to remove the large branches to prevent it would be a serious loss. For it is seldom that a large branch heals over readily, before the wound decays to the heart. There are some varieties too that scarcely ever droop their branches. Probably the best method would be to keep such trees by themselves, and allow the others, when large, to bend their limbs to the earth, as grass can not grow under such trees, and the ground is, therefore, always mellow.

An orchard, especially before the trees have attained the full size, never should be allowed to be covered with a stiff Timothy or red-top sod. In many parts of the country the injury done to orchards by grass is more than the value of the hay to the farmer, and he had best never undertake to have an orchard, if such is to be his practice. The roots of grass and the cereals, of which rye appears to be the worst, rob the young fibrous roots of their needed food and moisture. All hoed crops are best, and it would be better to alternate them, as potatoes, turnips, etc., one year, and corn the next. When the trees are too large to allow the planting of potatoes to advantage, corn for fodder and occasionally buckwheat may be sown. And when the trees nearly cover the ground, coarse manure should be occasionally spread on the surface and lightly plowed under in the spaces where a plow can go.

But this, as well as the amount of manure required, must be left to the cultivator's judgment, for the amount of nutriment in the soil adapted to the growth of trees varies greatly in different localities, but we know, if the ground be kept sufficiently rich by manuring to grow good corn and potatoes, the trees will get their proper share of it. Trees *may* be forced too much, and become weak and decay prematurely, although it very rarely happens from this cause. An occasional top-dressing with ashes will be beneficial—chips and dirt from the wood-pile, straw, cornstalks, or any refuse vegetable matter may be advantageously thrown under the trees when the plow can not be used.

WHAT VARIETIES TO CULTIVATE.

A very important question is: What varieties shall we plant? It costs no more time or money to raise the best than the poorest apples, and it is a question of some moment to the orchardist whether or not his trees bear apples that will return $5 or $1 per tree annually. There is no doubt that we have varieties enough now suited to each locality, did we only know them. Fruit growers are all aware that a superior variety in one part of our widely extended country is sometimes worthless in another section, and that, as a general rule, those varieties originating in any particular locality are best adapted to the soil and climate of that section. Again there are a few kinds that are deservedly popular nearly every where. Every person designing to plant an orchard should investigate the subject long enough to have a list prepared of those varieties that are adapted to his ground, before he goes to the nurseryman or agent. Nurserymen seldom cultivate an orchard; and as their information is gathered from many different and wide-spread sources, they may honestly recommend an apple to be excellent when it really proves quite an inferior fruit in the place the purchaser resides. Neither can this knowledge be reliably acquired from books, unless the authors describe what are good in each locality. Fruit books are most reliable too in describing the habits and character of fruits in the section of country in which the author resides; as for instance, Elliot for the fertile States of the west. Thomas and Downing for the middle States, and Cole for New England. In the early days of fruit culture many varieties of apples were brought from Europe, but with few exceptions, such as the Gravenstein and Red Astrachan, we now have far better varieties to cultivate originating in our particular sections. The best reference for the inquirer or reader will be found in the lists made out for the *Agriculturist* last year, by 77 different cultivators of fruit in various sections of the United States; and if a selection is made from those that received the largest number of votes, one can hardly go amiss. [See abstract of that list in another column.—ED.]

SUMMER APPLES.—*Early Harvest*, the most popular early tart apple throughout the country, is a slow grower and has the reputation of being short-lived. It should have the best soil and care, or the cultivator will be disappointed in its quality. The *Red Astrachan* is one of the very few foreign apples worthy of cultivation here. A very salable fruit, good bearer, but moderate growth. The *Early Bough* is a fine grower and bearer, and by some preferred as the best tart early sort. *Summer Rose* is excellent, but too small and a slow grower. *Summer Queen* is a good grower and profitable variety. *Summer Hagloe*, slow grower, handsome and profitable for market. Of sweet Summer apples the *Sweet Bough* is the most known. It is a good grower and bearer. *Golden Sweeting* is a better grower and more productive, not as good as the preceding for the table, though profitable for market. *Summer*

Paradise, large and straggling grower, and fine apple.

FALL APPLES.—I place the *Gravenstein* at the head of the list. It is a fine showy fruit-tree, an upright thrifty grower, and good bearer, and very salable. *Holden's Blush* is another pretty sort, and excellent for the table—far better than Hawthornden. *Am. Summer Pearmain*, a superior dessert sort, good bearer, but slow grower, needing a rich soil. *Porter*, a highly esteemed Fall apple, and when not too many on the tree, large and excellent. This is a very salable variety and the tree makes a beautiful growth. The *Rambo* is a fine apple in most places, but fails entirely in others. *Fall Pippin* is a fine old variety, but too uncertain for general culture—some years very fine, and again nearly worthless. Among sweet Fall apples the *Autumn Bough* deserves a place. It is a good grower and productive, excellent both for the table and baking. I have found the *Willis Sweeting* the best baking variety, and when fully ripe fine for the dessert. It is a good grower, and the fruit is in use longer than any other Autumn variety. *Jersey Sweeting* is a better table apple than the preceding, but not as valuable in any other respect. *Cortlet Sweeting* is a very thrifty grower, and is a good baking variety. *Lowell* is a fine grower, and is held in much esteem. *Fall Orange* is a strong grower, and bears very early; the fruit is excellent for stewing and dessert.

WINTER APPLES.—The *Baldwin* appears to have the highest reputation of any Winter apple growing in this country. It is a beautiful thrifty grower, and bears abundantly a rich fine fruit. Its nearest rival, the *Rhode Island Greening*, perhaps is more extensively planted than any other, and adapts itself to nearly every soil, and few need hesitate to plant abundantly of this fine old variety. Among the late keeping sorts the *Roxbury Russet* has the highest reputation. This is a good grower, and bears well. The *Hubbardston Nonsuch* is a large, beautiful fruit, and ripens in the early part of Winter. The tree is a fine grower, and abundant, regular bearer, an excellent, very salable fruit. *Peck's Pleasant* is a profitable variety, resembles the Newtown Pippin in shape, a better grower and bearer, but not its equal in keeping or flavor. The *Esopus Spitzenberg*, *Northern Spy*, *Newtown Pippin*, *Baldtwin*, *Swaar*, and *Vandervere* are most excellent varieties, when perfect. They succeed well in some localities, but are not adapted to all soils and climates. For sweet Winter apples I recommend the *Talman Sweeting* as a fine grower and abundant bearer; the *Ladies Sweeting* is a beautiful spicy fruit, and abundant bearer, but it is not a fast grower; the *Moore Sweeting* for its long keeping and excellent baking qualities; and *Pound Sweeting* for a large sized, productive, and salable variety.

Undoubtedly there are sorts of apples not named in the above lists better adapted to certain localities and soils, and we can not too urgently insist on the importance of those intending to plant an orchard, acquainting themselves with the kinds that have succeeded in their part of the country, and planting very sparingly if at all of those kinds that are unknown, however highly recommended they may be. The experience I have had fully justifies me in giving this advice to others, for many unprofitable trees of varieties good in some places I have been obliged to regrafi. The proportion of Summer, Fall and Winter kinds that should be planted depends upon the purpose and locality of the orchard. If for market chiefly, and accessible to large city, large and showy early apples are the most profitable, either sweet or sour. And if too great a distance to send Summer and Autumn apples to market with safety, large, prolific and well known Winter varieties should be selected. The red apples bear carriage best, as they do not show bruises like light-yellow or white apples, and appear to greater advantage when exposed for sale. Red Astrachan, Gravenstein, Summer Pearmain and the firm yellow Porter, appear well after a long journey. The marketman cares but little for the flavor or name of the fruit, provided it looks well when he receives it. When the orchard is intended chiefly for family use, beauty is not of much value, and smaller, high flavored and delicate apples will be most desirable. A few large coarse apples for stewing, may be allowed, but as a general rule fine flavored, tender fruit, is best for the culinary department too. Early apples seldom retain their flavor or good appearance long after they are picked, and the trees should be frequently visited either for market or for home use.

KEEPING APPLES.

Apples will keep better, if picked a little before they ripen or fall from the tree in Autumn. They should be kept in as cool a temperature as we can find above the freezing point, subject to as little variation as possible. After they are picked in the Fall, place them in a cool dry cellar with a free ventilation of air through it. They should not be covered up nor the barrels headed for two or three weeks after they are gathered, as they must sweat or throw off part of their moisture; if this is checked by close covering, a portion of the fruit will soon decay. If a proper cellar with good ventilation be not accessible, they may be placed on the back side of a building, as liable to vary least in temperature, or in a cool dry room. Those that fall from the tree before the time for picking, and all bruised fruit, should be kept from the sound apples. Various methods have been proposed for keeping apples, such as covering with dry sand, paper, sawdust, etc., but if placed among the fruit before they have sufficiently dried by sweating, they are productive of more harm than good. And no doubt this is the cause why some have succeeded, and others have failed. They did not understand this law. Pears, if placed in tight boxes and covered up soon after picking will ripen, and consequently decay much sooner.

Of the insects that are injurious to apple trees, the orchard or tent caterpillar makes its appearance earliest in the Spring. The female lays her eggs in the Summer, in a circle around the twigs, and if the trees are small, the most expeditious way is to examine the trees in Winter or early Spring and remove these collections of eggs. The eye will soon learn to detect these gummy, dark looking rings, and if destroyed before they hatch, much damage may be saved to the trees when first leafing out. Never let them remain on the tree until grown, as they will prepare much more trouble for the cultivator the succeeding year. Faithfully kept down from the first there will be little trouble afterwards. A pole with nails driven in the end with cloth tied around, or a stiff hair brush inserted in the nest early in the morning, and twisted round, will easily remove them. The injury done by the worm of the apple moth is not so easily prevented. Allowing pigs and cattle to run in the orchard, and eat the fallen fruit, or picking them up frequently and feeding them to the pigs, which is better, will reduce their numbers. For the apple tree borer, there can be no surer remedy than often inspecting the trunk of the trees near the roots for their holes in Autumn, and inserting either the point of a knife or sharp wire ferret out and destroy the enemy in his hiding place. Keep the bark smooth by proper culture, washing with strong soapsuds, or a weak solution of sal soda mixed with wood ashes, if mossy. A little time frequently devoted to careful inspection of the orchard will pay as good if not better interest than any other labor on the farm.

PLOWING ORCHARDS.

Always have the best and most careful plowman perform this business. Oxen are the best, no doubt, but as most farmers do not possess them, use the most steady horses. Plow alternately one year towards the trees, and the next from them. The good plowman will not allow the plow to run deep too near the trees so as to injure the roots, and will have shorter swiffle trees made on purpose to plow the orchard with. When these conditions can not be all secured, it is safer to prevent barking the trees, to leave two or three furrows nearest them, and afterwards finish with one horse and a short swiffle tree. As injury is often done in harrowing among trees, the driver should have a short rope attached to the harrow, to hold in his hand, so that by a pull he can throw it off, if it inadvertently comes near the tree

Best Apples for Different Localities.

It is now well understood that while there are a few good apples that are vigorous growers, and prolific bearers all over the country, yet as a general rule there are varieties which are peculiarly adapted to only limited sections, and in these localities such apples are the best for general cultivation. As the readers of volume 20 remember, we made an effort last year to gather the opinions of competent judges in regard to the best apples. Seventy seven lists were received, most of them from distinguished pomologists, horticultural and agricultural societies, etc. The reports were published in detail in the *Agriculturist* for April, May, and June, 1861. For convenience of reference, and for the benefit of new subscribers, we present below a condensed table of the votes or prefcrences expressed in the whole country, and by sections:

	VOTES GIVEN IN						
	From the whole U. S.	New England.	New York.	N. J., Pa., Md., Del.	Ohio, Indiana, Mich.	Wis., Illinois, Iowa.	Missouri, Ky., Tenn., Minn.

Broadwell	8	—	—	5	—	—	—

It will be seen that only three or four kinds received even a majority of the whole votes, and that in the different sections of the country, the preferences were considerably varied. Thus of Autumn apples, while 14 out of 17 authorities in New-York voted for the Fall Pippin, it received only 10 out of 16 votes in Ohio, etc. Of the Winter apples, the Baldwin received 17 votes from 17 authorities in New-England, and the same in New-York, while it received no votes at the West; the Yellow Bellflower stands highest there. These votes were from such good authorities that the above lists may be taken as a very fair indication of what are the *best* varieties of apples in the different sections named. A large number of the varieties were recommended, but we omit all that did not receive at least two votes. Each authority gave a list of the best six Winter apples (including 1 sweet), five Autumn varieties, and four Summer varieties. The table gives the total number of votes for each variety—single votes being omitted.

Beautiful Leaved Plants.

All over the world, the lovers of flowers and those who cultivate beautiful plants for the sake of their beauty alone, are now bestowing especial attention upon that large number of plants whose beauty consists in the various tints upon their *foliage*. Especial value being attached to brilliantly variegated leaves, plants exhibiting a tendency to sport in this way are encouraged in various ways to do so, and thus the number is rapidly multiplying. But these unnaturally variegated plants have generally a sickly look, and in fact many are really diseased, while those painted by Nature's hand exhibit a boldness and variety of coloring really startling. Our engraving shows as well as it can be done in black and white, the figuring of the *Sonerila margaritacea*; but beautiful as the cut is, it gives but a poor idea of the real beauty of the plant. The leaves are brilliant green, shading off in stripes into light yellowish green at the points and edges, and covered with pure silvery white dots arranged in rows. The under part of the leaf is light colored, with the veins of a brilliant red, as are also the leaf-stems, and the stalk. It is a native of Java, was introduced into England in 1848, and requires hot-house culture Winter and Summer. It is propagated by cuttings, and has pleasing rose-colored flowers. This beautiful little plant is only one of the multitude of beautiful leafed plants of which we often have something to say in the *Agriculturist*, but we know of none which so well admits of being represented in a wood cut. The beautiful *begonias, draccenas, calladiums, crotons, Cissus discolor*, and others, which are of easy culture, are becoming very common, and are among the most striking green-house ornaments. Besides, we have some *native* plants of great beauty of foliage which may well claim a place with these rare exotics. What is prettier than the ribbon-grass? A variety of the lily of the valley is beautifully striped, and not only do some kinds of ivy show light-colored veins, but some are variegated in white blotches very peculiarly. The horse-shoe geraniums are very brilliantly and regularly colored, as are also many other geraniums.

SONERILA MARGARITACEA.

May-Day Talk About Evergreens.

NEIGHBOR.—Good morning, my friend. True to my word, I have called for a chat about those conifers. Have you selected your evergreens?

GARDENER.—Havn't found time to write out a list, but have got one in my head. You are prepared to read off one, I see, by the paper in your hand. Please sit down, and proceed now.

NEIGHBOR.—I will do so, if you promise to give me your notes and comments, as I go on. I have given my trees in the order of merit, and have added some reasons for my preferences.

I. *Norway Spruce.* (*Abies excelsa.*)—Placed first on the list, because of its great general excellence. Not so neat, feathery, and graceful as the hemlock, yet easier transplanted, and more rapid in growth. Not so grand and flowing as the white pine, yet more symmetrical, bears removal better, and is more suited to the moderate extent of ordinary pleasure-grounds. It is hardy, more hardy, most hardy. Take it all in all, it is *the* tree for the people. So I think.

GARDENER.—The multitudes raised from seed, and sold every year in all parts of the country, prove its popularity. It makes a strong, coarse hedge, and a good wind barrier for a garden, if it be trimmed a little every year to thicken it.

II. *Hemlock Spruce.* (*Abies Canadensis.*)—Put second, only because it is somewhat hard to transplant, except when quite small. As to its intrinsic beauty, there can be no question; it ranks first among evergreens, native or foreign. Hardy, of course, since it grows wild on the hills in the cold regions of Maine and Canada.

GARDENER.—Right, again. Queen of conifers, is this home-born beauty. I like it none the less for its shyness in transplanting. It is too good a tree to be had without any painstaking. Right glad am I that it won't grow if set out like a fence-post. You didn't mention what a neat emerald hedge it makes. Begin with plants a foot high, cut them back well for several years, and the hedge or screen will become as impervious almost as the box-tree.

III. *The Pines.*—And first, the Weymouth Pine, (*Pinus strobus.*) An excellent tree for parks or large ornamental grounds—it may, also, stand near the margin of small yards. The pine foliage is heavier, more plume-like and silky than the spruce. The soft, silvery tinge of the white pine is one of its attractions.—The Bhotan Pine, (*Pinus Excelsa.*) resembles the Weymouth somewhat; but in many quarters it is rather sickly, and can not be highly commended.

The Austrian, (*Pinus Austriaca,*) is a noble tree, with dark, sea-green foliage, holds its color fresh and vivid through the entire Winter, is hardy as the hardiest, and is to be recommended.

The Oregon Pine, (*Pinus ponderosa,*) resembles the last, but is built on a larger pattern. It throws out its ponderous arms on every side, grandly, almost defiantly. In its very long leaves, it resembles some of those California pines which can not be successfully grown at the far north.

The Scotch pine, (*Pinus sylvestris,*) is worth a place in every collection of this family. It seems to be less pyramidal than most of the pines, and inclines rather to an irregular pear-form, with the stem down. As it becomes large, it strikes out into very picturesque shapes.

GARDENER.—You have left out the Corsican pine; but not unwisely, for it proves slightly tender at the far north. The *Cembrian* pine ought to be in every list, however small. It grows slowly, but is very dense in habit, has a fine, glossy green color, and perfectly hardy. There are others, but you have included the best.

IV. The *Silver Firs*, (*Picea.*)—South of 42°, the European Fir, (*Picea rectinata,*) is generally hardy, and very desirable. It has a striking statuesque symmetry. The Siberian, (*Picea picbta,*) has nearly or quite all the excellences of the foregoing, and is hardy further north. Fraser's Silver Fir seems to be a variety of the common Balsam Fir, which most surely will be planted widely.

V. The *Arbor Vitæ.*—The Siberian is confessedly the best member of this family. As hardy as the native, denser than that, of a darker and richer tint, and holds its color better in Winter. The common American *Arbor Vitæ* is one of the most serviceable of known trees. By a little pains in choosing specimens, one can get trees handsome enough for the finest lawn. Then, for screens and hedges, nothing is better. It will grow anywhere, anybody can transplant it, and it can be sheared into any shape. The *Siberian Arbor Vitæ* grows very compact, a beautiful cone, and is every way adapted for single specimens, or to be set in rows as a screen.

VI. *The Junipers.*—Of these there are many varieties. The Swedish is perhaps the best, for a wide range of latitude. The Irish is neater in style of foliage, but slightly tender at the north. The American is hardy, but coarser.

GARDENER.—I wonder the Junipers are not more generally planted. They are particularly well suited to small grounds and to cemetery lots. Their spiry, conical shapes throw them out in strong relief among other trees. But you have forgotten the American Black and White Spruce, and the Red Cedar.

VII. NEIGHBOR.—I intended to speak of them, and of several of the newer conifers which promise well. There is the *Thuiopsis borealis*, which is hardy through Central New-York, and very beautiful. Then, there is *Pinus Lambertiana*, and *Pinus Beardsleyii* and *Picea amabilis*, and *Picea Nordmaniana*, and others which will ere long find a place among standard trees.

GARDENER.—A good list, sir, for an amateur to make out. The latter part of this month is the best time to plant. Good morning; our May-day talk has been pleasant and profitable.

The Flower Garden.

In this merry month of May, the flower garden should *begin* to look attractive. The walks will, of course, be cleaned and the edgings clipped. The double Hyacinths, which have quite heavy flower stems, may break down in stormy weather, if not protected in some way. Wide shingles, set up on the exposed sides, will break off the wind somewhat. But they do not look well. A better way is to provide a bundle of slender, smooth stakes, about eight inches long, and to tie every flower stalk to one of these. Keep the ground loose and work it smooth between all the plants, including Narcissus, Tulips, etc. While the gay show lasts, make the most of it: it is, all things considered, one of the finest in the year, and will not come again under twelve months. As soon as the leaves turn yellow (not before,) cut them off close to the ground. Or, if you are very neat, and can not bear the first sign of slovenliness, as soon as *the tips* of the leaves become yellow, you may lift the bulbs with a narrow spade or a trowel, and set them ont temporarily in a retired corner. Then smooth down the borders, and prepare to set summer bedding-plants, or to sow annnals.

But does some lady lament that she has as yet no flower-garden? She has the ground, and seeds, and a few plants. But she wants a little instruction in laying out the borders, and in arranging plants in them. We snbjoin a few hints; but make haste, Miss Flora, or the season will get ahead of you. Several months ago, we gave a sketch of a plan worked out in onr own grounds, which looks well, and is easily managed. But for those who would like something different, we give another, (fig. 1), a favorite with Mr. Downing, and taken from one of his books. In such symmetrical gardens, it is not desirable to use coarse and tall flowers in any of the beds, as they would hide the others and destroy the general effect. Choose rather the dwarfish plants. For this particular pattern, it would be a good plan to set verbenas in the four outer beds: say, white verbenas in one, pink in the next, purple in the next, and scarlet in the last. In the small, central bed, put a sun-dial, or vase, or classic figure of any kind. An ornamental frame of some sort, with a delicate climber festooned about it, would look well. And perhaps a single row of verbenas or petunias might encircle this central ornament. The twelve other beds may be managed thns: every alternate bed devote to bulbs, set at a reasonable distance apart, so that as soon as the tops of the bulbs begin to wither, showy annuals may be set between them. They will completely cover the bed by mid-summer. Some of the best annnals for this purpose, are: Drummond's Phlox, Portulacca, Sweet Alyssum, Eschscholtzia, Collinsia bicolor, etc. The other six beds may be occupied with the various scarlet Geraniums, Heliotropes, Ageratum, Petunias, Pyrethrum and other bedding plants. These will keep the garden in a blaze of beauty all Summer. The walks of such a parterre should be made of the finest gravel, and always kept clean and smooth.

Fig. 1.

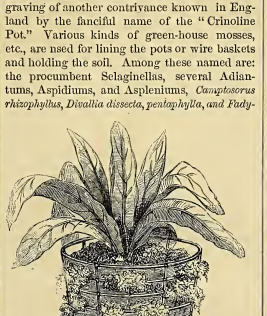
But some very sensible persons do not like perfect regularity and symmetry. They are picturesque in their tastes, and want their gardens to have a certain free and easy, rambling look. With an eye to the wants of snch people, we give the cnt fig. 2. This garden, it will be seen, is seclnded from the other parts of the

Fig. 2.

grounds, by low trees and shrnbs, irregnlarly grouped. It is entered by a covered walk, seen at *a*. The beds are cnt out in irregnlar patterns, yet so fitted to each other as to leave abont the same width of walk between them at all points. The walks may be of gravel laid over a solid bottom of cobblestones, or of smooth turf. If of the latter, the grass must be shorn and rolled once a week, and the verges neatly trimmed. The planting of the beds may be done in a picturesque manner—placing a plant here and there, without regard to size or character—some pains may be taken to assort colors, hights, etc. Quite a pleasing effect is produced by snch a garden.

Crinoline Flower Pots.

The Moss baskets, of which an account was recently given (page 20), are exciting, deservedly, so much interest that we present here an engraving of another contrivance known in England by the fanciful name of the "Crinoline Pot." Various kinds of green-house mosses, etc., are nsed for lining the pots or wire baskets and holding the soil. Among these named are: the procumbent Selaginellas, several Adiantums, Aspidiums, and Asplenimns, *Camptosorus rhizophyllus, Divallia dissecta, pentophylla, and Fadyensia proifera.* The plants that succeed best in these pots are heaths, ferns, all peat loving plants, and doubtless many others. Plants may be so placed as to protrude from any or all sides and even from the bottom, and, with the moss which clothes the soil, present a mass of beautiful verdnre, at times rendered still more attractive by bloom.



Transplanting Tomatoes, etc.

If tomatoes, cabbage-plants, and the like, are "pricked out" several times in the hot-bed or seed-bed, they will become more stocky, and will form a mass of roots which will make their final removal to the open grnnnd an easy matter, and ensure their making a speedy and rapid growth. (By "pricking ont" gardeners mean transplanting from a thick bed to give each plant more room to expand its tops and roots, and thns secure a more stocky habit. The roots of plants freqnently transplanted are likely to grow in a more compact mass, and endure this final removal better.) While still under the glasses, they should have as much air as possible by day time, to inure them to the atmosphere of out-doors. Jnst after a shower the ground is wet enough to refresh the roots, and the air is so moist that it does not exhaust the plants by rapid evaporation. But that good shower does not always come at jnst the desired time; the season is advancing, our plants are full grown, and ought to be in the garden; what shall we do? Do this: provide a number of old boxes, or a few dozen shingles, and have at hand a few pails of tepid water. Having stretched a line, make holes along side of it, where the plants are to stand, and pour a pint or more of water into each, leaving it to soak away. Take up your plants carefully with a garden trowel, preserving as much dirt as possible around the roots, and then set them in the holes, drawing fine soil aronnd them, and covering the stems a little higher than they stood before. Previous to finishing off, pour about half a pint of water into each hole, and then cover with common dry soil,—though this last watering is not essential. Shield each plant with a box or with shingles from the heat of the sun. The leaves may droop a little for a day or two, bnt they will revive again, and not a plant be lost. Following this method one can transplant these, and many other plants, whenever he pleases.

Poisonous Plants and Antidotes.

Poison Sumach, Poison Elder, Poison Dogwood, (*Rhus venenata.*) Poison Ivy, Poison Oak, (*Rhus toxicodendron,*) Climbing Ivy (*Rhus radicans*).

The poisonous aerid property of the milky juice of these shrubs is neutralized and made harmless by almost any alkali. When therefore one has been exposed to being "poisoned" by either of these plants, the parts exposed should be washed as soon as possible in a weak solution of potash, saleratus, soda or ammonia water, or even strong soapsuds. A piece of hard soap carried in the pocket to be used as occasion demanded might save a good deal of after torment. White lye forms a very simple and a very complete protection against the poison of Dogwood, or Ivy. It is made, as almost every body knows, by putting a couple of shovelfuls of hard wood ashes into a pail of water, stirring it up well and standing it aside to settle. Before going out to work among Dogwood or Ivy, wet the hands, arms, face, and legs, so far as may be necessary, with the lye and let it dry on the skin. You may now work among the vile stuff without harm. Take care not to make the lye strong enough to injure the skin, the same caution must be observed in the use of the alkalies named above. When the poisonous juice has been in contact with the skin for some time and specially after the inflammation has set in, it may be doubted whether its action can be controlled, the poison must run its course. Indeed if much of the surface of the body is affected, it will be very unsafe to attempt to drive it away. I once met with a case where the eruption left the skin and settled upon the lungs, throwing the patient into great danger of speedy death from congestion of that organ. Very active treatment re-

lieved him from the present danger, but it was months before he got rid of a troublesome and alarming cough which followed. The sufferer must keep cool—live on water gruel—call to his aid all his patience and bear his torment as he best can. A moderate dose or two of Epsom salts will serve to cool the blood and to keep the eruption from running into bad sores or ending in a crop of boils.

K.

The writer adds in a note to the Editor: "I have suffered severely often—and once dangerously from the plants named above, and know from trial and experiment the neutralizers of the poison."

Vinegar—Acetous Fermentation.

The sharpness of vinegar is due to acetic acid which it contains. Its color and flavor, aside from the sourness, are due to the other ingredients of the cider wine, or any thing else from which it is made. Acetic acid is only produced from alcohol, which, absorbing oxygen from the air, becomes acetic acid. Alcoholic liquids will rapidly turn to vinegar if exposed to the air, and themselves thoroughly exposed, the more rapidly will this, which is called the *acetous fermentation*, proceed. Warmth also greatly promotes it, and any fermenting body diffused through any liquid containing alcohol causes it to go on more rapidly. Good cider vinegar contains only about 5 per cent. of acetic acid; it is very strong when it contains 6 to 8 per cent, and the best wine vinegar contains only 10 per cent. This renders it necessary where vinegar is transported far, to carry 93 to 95 per cent. of water, and so, of course, it is much cheaper to carry the strong acid and make vinegar by adding it to water at the journey's end. "Distilled vinegar," or acetic acid lacks the pleasant flavor of good cider vinegar and has only the peculiar taste of the volatile pungent acid itself.

When cider is set for vinegar, place the barrels in a warm shed, or even in the open air, on the sunny side of the house, tack some gauze over the bung-holes, to keep insects out, and it will soon become vinegar. The addition of "mother of vinegar," which is a fungus plant (*Mycoderma aceti*), seems to give an impulse to the fermentation, and the same be given by a quart or two of good strong vinegar drawn from the bottom of the barrel; but if the cider has any proper strength, these additions are of no advantage, and if it is weak they are apt to produce moldiness.

For the American Agriculturist.

Hints on the Art of Butter Making.

In order to make pure butter, something is required besides the good breed of cows—the sweet grasses—the soft springs—the rolling lands—and the rich milk, and the most experienced churners—the most improved machinery—the purest atmosphere—the best material may be manufactured into yellow grease instead of butter, unless the process be properly performed. It is a fact well known to scientific dairymen, that the pure butter is *not made by agitating the milk—not made by the process of churning. Butter already exists in the milk*, and the art of separating it from the milk, is that on which the success of the dairy depends.

Butter exists in globules so small as to defy the detection of the eye unaided by the microscope, and the removal of these globules without crushing them, is the delicate and difficult task the dairyman has to do. There is no luxury that comes to the table which is so exquisitely sensitive as butter. If the cow feeds on white clover, the butter has a white clover flavor; if she feeds on cabbages, the butter has the flavor of cabbage; if the butter is kept in the vicinity of the stable, it forthwith becomes tainted with the smell of the stable; if packed away in pine tubs, it catches the taste and odor of the pine. It requires skillful handling or it will certainly be spoiled. If there is too much rubbing in the churn, these fine globules, mashed and crushed against the sides of the churn, will give greasy butter; and if the air is excluded the gases will injure it. What can be done, you inquire, to cause the adhesion of the globules without grinding or breaking them. Experienced churners answer the question, when they caution young beginners not to churn too fast, not to heat the milk too much, not to overdo, etc. They may not in every instance understand the philosophy of the fact, but they do know the fact, that "overdoing" makes grease and not butter. The seasoning of butter is a matter of taste, and there are a great many persons who imagine that the more salt they put in the butter the better it keeps. That is a great mistake. Just enough and none too much is what is required. [Few indeed, even among butter makers in this country, know the luxury of *fresh* butter with no salt at all.—ED.] Too much will spoil the taste and not save the butter. Without penetrating any deeper at present into the philosophy of butter making, I will simply add that, a gentle and uniform agitation of the milk will best reward the butter maker for his pains. [The cream should have a temperature of about 65° F. when churning begius.—ED.] The butter should be kept away from all unpleasant odors, and when put down should be packed in white oak tubs.

Clean cows, clean stables, sweet churns and pans, neat and tidy operators, are among the things desired by those who would send pure butter to market.

GEO. W. BUNGAY.

Grease Spots.

A grease spot on many delicate fabrics is a difficult thing to remove, on others it comes away very easily. When first made, before the fibers have thoroughly absorbed the grease, soap of almost any kind will often quickly remove it; after a few days, a soap of peculiar quality is required. The hardest and whitest is commonly best, and softsoap is the most powerful, but thickens or changes the color or weaken the texture of the goods. Turpentine, kerosene, and other carbonaceous liquids, have a great affinity for grease, and dissolve it, but are themselves so difficult to remove from cloth that by their use we are apt to only diffuse the grease over a larger surface. Ether, chloroform, and to a limited extent, alcohol, dissolves grease, and though they do not remove it any better than turpentine, yet they bring it into a condition to be easily washed away by soap and water. On fabrics not injured by alkalies, ammonia water used to wet the spots, renders them easy of removal. Ox gall is a soap of a very delicate, mild character. It will sometimes remove grease, and other spots from silks, and other delicate fabrics, without injury to the colors, when every thing else fails; it is itself easily washed off. Almost any very fine soft substance will absorb grease. The articles most in use and very effective are, potter's clay, French chalk, common chalk. These are scraped upon the spot in fine powder, or wet up to a paste and laid upon it, and then by application of a hot-iron in close proximity, the grease, even though it be wax or spermaceti, is absorbed by the clay and may be washed away, and all removed after a few patient applications. In the absence of clay or French chalk, or on fabrics likely to be injured by them, any bibulous paper (such as will quickly absorb water, like blotting paper) may be laid upon the spot, and a hot-iron being applied, a great part of the grease will be taken up by the paper, and the rest chiefly diffused so as not to be seen.

Cocoanut Shell Hanging Basket.

Miss E. M. Powell, of Ghent, writes to the *Agriculturist:* "A very pretty hanging basket can be made by sawing off about three inches from the smaller end of a cocoanut, removing the meat, and covering the ontside with the green, the cup, and the wood mosses. These may be fastened to the shell with a solution of gum arabic, made very thick. I have one containing moneywort (growing in the shell) which droops gracefully over the sides, and a verbena which is now (March 23,) in bloom. These cups or baskets are very easily and quickly made, and they are very beautiful."—[The shell is of course suspended upon a string which may be attached to the upper rim of the cup by means of small holes. Small vines or moss may be trained up the strings. See page 212, July *Agriculturist*, 1861. These ornaments cost little or nothing, and they add much to the cheerfulness of a room. They are as good as medicine in the room of an invalid.—ED.]

Stone Jugs vs. Tin Cans for Fruits.

W. B. B., of Southern Minuesota, writes to the *Agriculturist* thus: "Here at the West, tin cans cost at least 33 cents per gallou, and can be used but once, to which must be added cousiderable more if you live far from the tinman. The "self sealers" cost 45 cents a quart here! Stoue jugs cost only a "York Shilling" (12½ cents) per gallon, and will last for years. On three years' trial we find the jugs preserve fruit better than tin cans. We fill the jugs while standing on a hot stove; and while the contents are boiling hot, close them with a cork or nicely fitting plug of soft wood, covering with melted sealing wax or resin."

[REMARKS.—After using hundreds of tin cans, common and self sealing, we have discarded them entirely, and advise others to do so, ou account of the danger there always is of the corrosion of the tin and the productiou of poisouous salts. Well glazed stone ware, jars, bottles, or jugs, answer well. We prefer glass, however. The dark colored glass is cheap. We use wide uecked bottles, one and two quart sizes—mostly quarts—corking while hot, wiping clean and dry, and coverlug with cement made of one pound of resin with about oue ounce of tallow melted together. The bottles are then set necks dowuward in small tin patty pans, costing a penny apiece, or in old saucers if these be on hand, and cement enough is dipped in to completely euvelop the top of the bottle neck. This entirely shuts out access of air. If the bottles be filled with hot fruits, and be corked and sealed while still hot, the pressure is always *inward*, but the tin or saucer covers prevent the cork being forced in by the air. We merely heat the fruits *through* in a kettle, dip them into the jars, or glass bottles of any kind, and seal as above. The experience of two years proves this mode to be the cheapest *and best*. But more full particulars next month.]

About Unleavened Bread.

To the Editor of the American Agriculturist.

I believe it is generally admitted that yeast, cream of tartar, and saleratus do uot add any nutritive properties to bread. But it is also as generally believed that good bread can not be made without them. This I think is a mistake. Certainly some of the best bread I ever tasted was made as follows:

No. 1. Take wheat flour (either Graham, or flue,) and pure soft water, and make into a very *stiff* dough, roll out from half to three-fourths of an inch thick, cut into cakes two inches or less square, or round like crackers, prick them through several times with a fork (to prevent blistering), pass them into an oven sufficiently hot to bake wheat bread, and keep up the heat for twenty minutes or more.

No. 2. Mixtures of corn, rye, oats, and barley flour. If any one of these alone, on any two or three of them in almost any preparation, be mixed with pure soft water and baked as directed in No. 1, an excellent bread will be produced.

Bread made according to the above directions and thoroughly dried in the air after baking, or better, in a warm oven, will keep for many months, and lose none of its natural taste or good qualities, especially No. 1. Remember that nothing but water and flour, or meal, not even salt, is added in making unleavened bread; neither is the dough allowed to rise before baking. It rises while in the oven. This bread is not so soft and spongy as fermented bread, yet enough so for persons having good teeth. Those having poor masticators can soak it in water or milk, or in any way that they would use common crackers. If properly prepared, this bread does not loose its *sweet natural taste* by long keeping, nor can it sour, as is sometimes the case with raised

bread. Do not be discouraged if the first trial prove a failure, but try again. It is not uncommon even for experienced bakers to occasionally get a poor batch of raised bread. We made very many trials before we properly understood it. Now we are more sure of good bread every time we bake, than in the old way. E. W. KNIGHT.

Glenns Falls, N. Y., March 4.

REMARKS.—We give the above, not to endorse it especially, for the taste of people generally would require to be greatly changed, before they could be brought to substitute for light nicely raised bread, the hard unleavened water-mixed cakes. It can not be denied, however, that so far as health is concerned, the pure unbolted ground meal of wheat or other grain, is better adapted to the wants of the body than the fine bolted flour. But there is one consideration not taken into account by those who would discard yeast-raised bread. To enter into the blood as nutriment to the body, food must be digested, that is, its chemical structure must be changed, and a new arrangement of its elements be produced, which is equivalent to saying it partly decays in the stomach so that its elements, simple and proximate, may enter into other combinations. The fermentation (raising by yeast) is a step in this decay or destructive process, and it may well be queried whether fermented bread is not better adapted to digestion than unleavened bread. The yeasting, fermentation, or raising of the bread, is so much work done in advance for the digestive organs of the stomach. The baking merely stops the destructive fermentation at a particular point, to be resumed again when brought in contact with the gastric fluid. If this view be correct, sour bread—that fermented to excess—may be quite as healthful as the sweetest. It certainly goes through a souring, destructive process in the stomach, before it gets into the blood as nutritative chyle. So far as health is concerned, those people who habitually use sour bread, from want of skill, or from preference, do not appear to be less healthy, or to suffer more from indigestion than other classes. As for the taste in the matter, that depends mainly upon habit. The writer above has learned to like the hard unleavened cakes, and doubtless enjoys them. Another learns to like the sharp acid flavor of sour bread, and esteems your light sweet bread as insipid. The latter is the case generally with the people of Central Europe.—ED.]

Old Fashioned "Hulled Corn."

"Aunt Mary" of Colchester, writes to the *American Agriculturist*: "Some of the old fashioned ways of using corn, in vogue when wheat flour was almost as scarce and precious as gold dust, are worthy of being called to mind now, especially by those who do not relish corn bread or 'hoe-cake.' Here, for example, is my old and my present way of hulling corn, which furnishes a dish that would have pleased Mr. Smith, and perhaps have made him outgrow his suspenders in half the time mentioned in connection with his picture in the *March Agriculturist*.—Take about as much ripe dry corn as would be shelled from a dozen ears, and put it in an iron kettle, covering it with cold water. Tie in a cloth or small bag about two teacupfuls of good wood ashes; put the bag in with the corn, and boil until it looks yellow, and tastes pretty strongly of the alkali. Take out the bag, and boil the corn slowly in the lye for an hour or so; then pour off the lye and add cold water, and simmer until the corn swells. If the hulls do not then come off by stirring, turn off the water and rub the corn in a clean coarse towel, which will remove most of the hulls. Again add more water and simmer for several hours, stirring often to prevent burning. When it swells out large, becomes softened through, and looks white, add salt to the liking, and let the water cook nearly away. Eat warm or cold, with cream or milk. In cold weather it will be just as good when several days old."—[We agree with 'Aunt Mary' that this old fashioned hulled corn is a good dish. Rightly prepared, it is as soft and delicate as green corn in the ear, though it has not the sweetish taste. Unless plenty of water be added to thoroughly wash off the alkali after the hulls are loosened, it will not suit the taste of some persons. The salting is an important part also. Most persons leave it too fresh, though we have tasted it when spoiled with excess of salt. It is a little troublesome to prepare, but is cheap, and good enough to pay for the labor. We wish 'Aunt Mary' was our next door neighbor, so that we could often drop in for a dish of the old fashioned hulled corn, that in our boyhood we considered as one of the greatest luxuries, but which has seldom been met with in later years.]

Corn Bread Questions—Explanations.

Many inquiries are made for *particulars* concerning the various corn bread recipes published in the first three numbers of this volume. We can not answer them; the contributors mostly live at too great a distance to be personally consulted. We published the directions just as given, or with emendations in the words and style only—not in the prescriptions. A few write that they have followed the directions, and yet can not produce good bread or cake, and intimate that there must have been some mistake or deception. We take it that none of the contributors would give directions different from these by which the actual specimens sent were made. A great deal depends upon the skill of the operator in using any recipe. Two persons will often produce a very different article of food, though both try to follow precisely the same directions. Comparatively few housekeepers make every batch of bread from the same barrel equally good, though intending to pursue the same method in each baking.

Pot-Pies.

A good pot-pie is a good thing; heavy, half-cooked dough is poor eating, and hard to be digested, whether cooked in the form of bread loaves, biscuits, or in a kettle. A lady reader of the *American Agriculturist*, whose pot-pies we have proved and approved more than once, writes out the following directions: Make the dough just as for raised biscuits; an egg, beaten and mixed in with the butter or lard shortening, improves the lightness and quality, but is not necessary. When the meat is boiled nearly enough, cut the dough into small biscuit size, and lay the pieces not among the meat, but on a perforated tin placed in the pot just above the liquid; cover and cook them through by the steam. Stir a little flour into the meat liquor and boil it well; lay the cooked crust on the dish and pour over it the gravy and the meat.——(2) Mrs. Lucy Upson, of Pecatonica, Winnebago Co., Ill., contributes the following: "For the crust, use 1 pint of sweet milk, 1 teaspoonful of soda, 3 teaspoonfuls cream of tartar, butter the size of an egg, and flour enough to make dough as stiff as for tea-biscuit. Roll out and cut like biscuit and drop on the top of the chicken, cover and boil 20 minutes."

MEAT FOR POT-PIES.—Tender poultry is of course preferable, when to be obtained; but almost any kind of meat not too fat, answers well. Good veal, and lamb, are next to poultry, but beef, lean pork, or spare-rib, or any kind of lean meat is far from a poor substitute, if the crust be made light.

Salad Dressing.

It is a great art to make a good dressing for green salad—lettuce or endive. The art consists in mingling the various ingredients so that each will become disguised and in its turn disguise the others while the combination in no wise obscures the delicious flavor of the lettuce or cadives—but rather augments it and promotes its digestibility.... Take the yolks of two hard boiled eggs, crumble them with a silver fork or dessert spoon, add about half a teaspoonful of ground mustard and a teaspoonful of salt, and mix all well together. Then add in three portions a dessert spoonful of pure olive, walnut or poppy oil, and rub the whole to a uniform smoothness. The addition of twice the quantity of oil will improve the salad to the taste of many, and nothing is more healthful; a dash of cayenne pepper, or a few drops of pepper vinegar may also be added; finally add about a dessert spoonful of sharp vinegar, and if the dressing is not fluid enough, a little water or more vinegar, adding it gradually and rubbing thoroughly all the time. A little experience only is necessary, but it requires tact and patience. Most people abhor oil because they pour it over the green leaves instead of blending it in a dressing. Others douse on oil, catsup, mustard, pepper, salt—every spice or condiment they can lay hands upon—sugar it well besides, and then drown it in vinegar. Think of catsup on a crisp lettuce head—horrible!

*

Greasing a Griddle—The Best Way.

"Letty Ermin" of New-York, writes to the *Agriculturist* thus: The soapstone griddles require no greasing, but the "flap-jacks" are insipid. Too much fat is equally objectionable. The piece of fat pork commonly used becomes blackened and seared to bitterness—disagreeable to the eye, at least. The very best greaser is a linen swab, dipped into nicely tried drippings, or suet warmed, and rubbed quickly over the surface.—This same kind of "swab" of smaller size, is also the best thing for greasing bread pans, and for fitting into the corners and scallops of cake forms.

"Pot-au-feu" Recipe direct from France.

MONTARGIS, France, March 12th, 1862.

MR. EDITOR: Seeing in the January *Agriculturist* an inquiry for a recipe for the French "Pot-au-feu." I send one that is good, and at your disposal. Although so far away from our native land, we think we cannot do without your most excellent journal.

To 1 gallon of water, put 4 lbs. of beef, 3 tablespoonfuls of salt, and 1 of pepper; set it on the fire, and as the scum rises, skim it until clear. Then add 2 carrots, 2 turnips, 2 leeks, cut in pieces; 2 onions, in one of which stick 3 cloves; 1 burnt onion, or other coloring. Boil gently 5 or 6 hours. The broth, with good wheat bread, vermicell, or tapioca, is good enough for any table. The meat is to be served afterward with the vegetables. E. M. L.

Laurel Leaves, mentioned in a recipe for Pot-au-feu on page 86, are not leaves of "ground laurel," "high," nor "low laurel," nor of any other wild plant called laurel by our country folk, but the common European laurel, or bay laurel, *Laurus nobilis*. It is cultivated sometimes in this country, and we are familiar with the leaves, which are often used in packing fig drums.

Breakfast Cake.

Mrs. Bennett, Ripley Co., Ind., recommends: "2¼ cups flour, 3 well beaten eggs, 1 teaspoonful salt, and sweet milk enough to make a stiff batter. Add the eggs last. Put in a hot, greased pan, and bake until brown."

Cheap Cup Cake.

Contributed to the *Agriculturist* by some one whose name is not on the recipe. "Take 3 cups of flour, 2 cups of sugar, 1 cup of butter, 4 eggs, ½ cup of sweet milk, ½ teaspoonful of soda, and 1 teaspoonful of cream of tartar; flavor to the taste."

Corn Meal Pudding.

By same as above: Take 1 quart of mush, and cool it with new sweet milk (not quite as much milk as mush), 5 eggs, ½ teacupful of sugar, 1 teacupful of flour, a little salt and soda or quick yeast, and ground cinnamon if liked. Bake 1 hour in a moderately slow oven, and eat with sauce. Some prefer to use no sugar in the pudding itself, but to eat with butter, sugar and nutmeg mixed.

Indian Meal Pies. Contributed to the *Agriculturist*, by Mary Williams, Linn Co., Iowa: Stir a small teacupful of very *fine* ground Indian meal into 2 quarts of boiling milk. When nearly cool, add 5 beaten eggs, and sweeten to taste, like a custard, adding spice and orange peel, if desired. Bake with a crust, the same as custard pies.

A DISTURBED NAP—FROM A PAINTING BY J. L. HAMON.
Engraved for the American Agriculturist.

The Editor with his Young Readers.

The above picture is not presented to our young readers as an example for them to follow, but simply as a sketch of real life. Tired of his toys, the active little fellow is wide awake for some excitement. How quietly he slipped his shoes off and moved about the room, and by taking thought, and a foot stool, succeeded, after a fashion, in adding a cubit or less to his stature, and thus the mischievous elf found at last an outlet for his pent up fun. He has weighed well the half-in-jest scolding he will get and come to the conclusion that the fun is worth all it will cost. Well, we sympathize with the little fellow, and though confessing it is not the pleasantest thing in the world to be waked up out of a pleasant nap in such a way, would forgive the child more easily than some naughty blue-bottle fly that might do very much the same thing. *Genuine* fun, even that which might be called mischief, *if free* from any willingness to really trouble others, shows the working of a bright active mind. The element of fun in the disposition is an admirable trait, and we would by all means treat indulgently errors having their source in good natured frolics. True, the respect due to age and to parents is not always a sufficient check, and sufficient regard is not had for the times and seasons when a frolic is most desirable; but such familiarity is far better than the shrinking awe with which many children regard grown people. Children should enjoy their parents' society more than any other; and he who can appreciate the fun and frolic of his child, lives his own life over again. The warm, pleasant Spring days are here, and the children are now no longer housed with their rocking horses, dolls, and wooden warriors, but are abroad, with nimble feet climbing the banks and walls in search of flowers and health, discovering beetles, bugs, and birds' nests, and leaving us to discover the tears in their clothes, and the many black and blue spots from unremembered blows and buffets, received in their tussles with the bushes and the rocks. It is all good for them, and a hard knock now and then will do little harm, while mamma's afternoon nap will be far less frequently disturbed.

Letter from a "Pretty Old Boy."

MR. EDITOR:—I suppose you are much younger than I am, so far as years are concerned, for I judge that you are in the prime of life as they once called me; while I have got far beyond that. The old adage is: "Once a man and twice a child;" but I have been three times a child—once when from five to twenty; once when from fifty-five to sixty I began to play with my grand-children, and now at eighty two I am playing with my great-grand-children. I feel very much like a child, and good times I do have with my loving great-grand-children up here in New-Hampshire, for they love me, and I love them, and we play and talk a great deal together, and they read to me all in the boys and girls' department of the *Agriculturist*, and I tell them all about my long journey through life thus far, and try to teach them many useful things, too. You are younger than I, yet you can teach me a great deal along with your *other* boys. When I was first a boy, and then a young man, there were not any papers for the young people, and there were few schools, and fewer books, and so I could not learn much. Well, what I am trying to get at, is this. The other day I was telling our young group something about what you call "chemistry," that is, about the wonderful way the Creator has put things together—the stones, the soils, the plants, the water, the air, and even our bodies. But I got bewildered myself, and now I want to ask you to tell us boys, and the girls too, something about chemistry. We could read about it in books, but we prefer to have you to talk it to us in your plain, easy way. You will thus oblige some grown up people, and the young boys and girls, and especially—

A PRETTY OLD BOY.

What think you of that, young friends?—one who has seen *eighty two* Summers and Winters, eighty two Springs and Autumns, and yet considers himself a boy, and is desirous to still learn something of the wonderful works of God as displayed in the curious mechanism or composition of the things around us. Pretty soon, though for the sake of that group he gathers around him we hope it will be many years hence, yet pretty soon he will be transferred to a state where he will know far more of God's works than the wisest of us can conceive of here. When we think of his long experience and what he has seen and learned of the ways of men, we would gladly sit at his feet and gather lessons of wisdom such as only age can teach. Still we will adopt his suggestion, and in the best way we can try to tell you

Something about Chemistry.

First, let us collect a few things as examples. Here is an iron nail; here is a leaden bullet; here is a slip of zinc; and here, each by itself, is a bit of copper, some quicksilver in a vial, and a lump of charcoal. Let us begin with the iron. We hammer it, cut it, heat it, file it into the smallest dust, and it is only iron. Each finest particle is still a perfect piece of iron. We can make nothing of it but iron, *unless we add something to it.* Nobody has yet been able to make anything of iron but iron, without adding something else. We say, then, that it is a *simple body—an elementary body*—it has but one element or one kind of particles or atoms in it, and these atoms are all iron and only iron. If we take the lead, the zinc, the quicksilver (mercury), and the charcoal, and treat them in the same way, the result will be the same. In one we can only find lead, and nothing else; in the next only zinc atoms; in the next only copper atoms; in the next only quicksilver atoms, and in the charcoal (carbon) only atoms of charcoal. These then we call simple bodies or *elements*—things that can not be separated into two or more other things. It may surprise you to learn, that there are only about sixty of these simple or elementary bodies in all the world!—Now take a little piece of dry wood, a match will do, light the end and let it burn under a cold glass tumbler turned over it. See! The wood turns black and soon we have only a bit of charcoal left. But on the inside of the tumbler we have a moist dew (water) collected. The fact is, what was formerly wood has now been changed into charcoal and water, with besides a little of another substance that has escaped in the air unseen. Just as the water would have gone off had it not been caught and condensed by the glass. Our wood then is a *compound* substance, made up of at least two other substances, charcoal and water, both of which are unlike wood: wood then is *not* a simple, elementary substance. The chemist can go further; he can take the water and separate it into two other substances neither of which is at all like water; out he can not do the same with the charcoal, for that is one of the simple elements out of which other things are made.—Almost all the things we see about us are compound bodies, made up of two or three, or more, other substances, just as cake is made up of flour, milk sugar, butter, eggs, salt, etc., though any body who did not know how it was made would never dream that there were so many things in a bit of cake. *Chemistry* tells us some very curious things about the simple or elementary substances, and the way the elements are put together to make different *compound* substances. It tells us how compound bodies can be taken to pieces, and their elements be put together to make other very different compounds. It tells us how only fifteen or twenty simple or elementary substances are curiously put together to produce nearly all the things we daily see around us. It teaches us many lessons very useful in our every day life. We shall find that we are really practising chemistry con-

Shadows on the Wall.

stantly, and that our comfort depends much upon chemical operations, and that by just so much as we learn to practice chemistry, by so much will we promote our comfort. Chemistry is intensely interesting, as well as useful. The world looks a very different world to one who has learned to look into the way its thousands of objects are made up. It is not a difficult study when rightly taken hold of. There are a few letters of the chemical alphabet to be learned before you can read the science, and practice it. Until our next lesson, please remember the first two letters, viz.: *A. A* simple body, called an *element*, one which can not be separated into two other substances. *B.* A compound body is one which can be divided into two or more different substances.

SCENE OF THE BATTLE GROUND OF PITTSBURG, OR SHILOH, TENN, APRIL 6th and 7th, 1862.

We again throw over some pictures, puzzles, and stories, to make room for Maps of localities of intense interest and importance at the present time. (See pages 156 and 157). Study them well. We hope soon to have no more special occasion for these now very useful maps.

Last month (p. 129) we gave two sh[illegible]r Pictures to be ma[illegible] the hands, and hay, other[illegible]prepared of the same kind; but we lay them [illegible] to ap[illegible]r time, to make [illegible] for a very fine card-board picture, the original of which was sent to the *Agriculturist* by Mr. J. Fill, Principal of Bladensburg Academy, Md. Mr. F. will see that we have improved somewhat upon his pattern.—This is easily used, and we make it of the full size for marking out. Lay over this picture a thin piece of paper, and with a pencil trace the outlines, rounding the eyes, etc. With the pattern thus obtained, mark out the picture upon a thick piece of card-board, or pasteboard, or any paper thick enough to let no light pass through it; the cover of a ribbon or other box will be just the thing. It will improve your taste to transfer the picture by the eye. Cut the holes squarely through the card-board with a sharp pointed knife. For light shading on the hair and chin or beard, make slits very narrow. You will improve your skill in studying light and shade, by puncturing the card with pin-holes on the forehead, beard, the side locks, etc. Hold the card-board squarely between a single strong light and a white wall, and the shadow will be very pretty. Vary the relative distance between the light, the card, and the wall, to produce the clearest picture. Different kinds of light will somewhat vary the appearance of the shadows.

The Mississippi River—Distances.

As we now write, many eyes and hearts are turned towards the Mississippi River and Valley. Few of our younger readers have any idea of the real magnitude of this great stream, which receives the water from about seven hundred million acres. We have had the pleasure of going both up and down on the Mississippi, from St. Paul, Min., to New-Orleans, and we confess that all we had read in our geographies, and elsewhere, gave but a faint idea of its vastness. Think of a lake *from one to two miles wide*, often more, and a thousand miles long, and you have some idea of the Mississippi between Cairo and New-Orleans. The river is exceedingly crooked, now running this way and now that; sometimes you are going down stream, though sailing directly north. In a few places the channel bends round so that, after running 10 to 30 miles, it comes back to within two or three miles of itself. So crooked is the course of the river that, though it is only about 475 miles in a direct line from Cairo to New-Orleans, yet the distance by the river is 1046 miles. There are many islands in the river. For convenience these are numbered, beginning with No. 1 for the first island below Cairo at the mouth of the Ohio river, and so on down to the Island No. 10, and to Island No. 150, near New-Orleans. But we have only room now for the following table of distances, which will be useful while we are watching the course of the armies. The following distances in miles are by the river channel:

	From Place	From Cairo	From New Orleans.
St. Paul		695	2035
Red Wing	37	949	1780

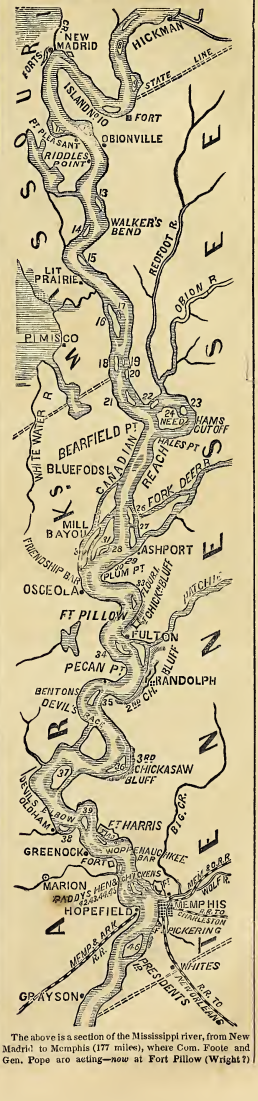
THE MISSISSIPPI,

FROM NEW-MADRID TO MEMPHIS.



The above is a section of the Mississippi river, from New Madrid to Memphis (177 miles), where Com. Foote and Gen. Pope are acting—*now* at Fort Pillow (Wright?)

Market Review, Prices, etc.

The course of the Breadstuff Markets, during a few weeks past has, utterly set at naught the calculations of the best informed statisticians and dealers. With the *known* large deficiency in Europe, to be made up before harvest, prices have continued to decline, almost daily. The only explanations to be given, are: 1st. The great falling off in our importations of European manufactures, (over $100,000,000 in a year past) has reduced the means of foreign operatives so much, that they are now consuming vastly less of wheat, and flour, and eating more of cheaper, coarser food. Since Jan. 1st, they have taken **4,170,100** bushels of our *Corn*, against only **2,419,500** bushels during the same period last year. —2d. The heavy dealers, here and abroad, in expectation of a large advance, purchased more stock than they could easily carry, and a slight decline seriously embarrassed some of them, and forced them to sell. This disturbed the trade, and compelled other holders to realize, and the market has thus been greatly depressed and unsettled.—3d. The excellent weather abroad has led to the putting in of large crops of Spring wheat, which has acted somewhat upon the fears of dealers, though this new sowing can not come in to meet any immediate demand.—4th. The farmers of Great Britain, and in Europe generally, have improved the favorable weather of the Winter, to thresh and market most of their grain—a much greater proportion than usual. This, while supplying the immediate wants, will leave much less for the demand during the next three or four months. But every indication is, that there will, on the opening of inland navigation, be a new impulse to the Breadstuff trade, and a material and immediate advance from present low rates. Indeed, the upward movement appears to have already begun, there being a rise of 5 to 15 cents per barrel in flour, within two days......Cotton was dull and heavy early in the month, but has been in good request during the past week, and closes buoyantly, at 28c.@29c. ℔ lb. for Middlings . .. A very brisk export trade was transacted in Provisions until within a few days; recent unfavorable advices have checked the foreign demand, the market closes heavily for hog products, though steadily for other articles ... Hay, Hemp, Hops, Rice, Seed (except Clover) and Tobacco have been in limited request at irregular prices. Clover Seed was dull of sale, at low figures, a few weeks ago, but recently the demand has been unexpectedly large, while the receipts have been small, and the temporary scarcity rapidly carried prices up fully $1 per bushel (60 lbs.). The market is apparently more quiet just now, and rates are a little below the highest point recently obtained.. .The private sales of Wool were very moderate at former figures. An important auction sale occurred in Boston, on April 10th, when about 600,000 lbs. of fine Ohio and Pennsylvania fleece Wool were sold. The attendance was large, all the leading manufacturers in New-England having been represented and the entire lot was rapidly disposed of, at, on the whole, satisfactory prices. Large lots of extra and double Ohio and Pennsylvania sold for 44c.@46c.; extra Ohio sold at 43c., and a lot, very light, at 46c; double extra Ohio, very light, for 46c.@48c.; Ohio picklock, 49c.@50c.; a small lot choice Pennsylvania picklock, 51c. Washington County fleece, 44½c.@46c., and one double extra at 47½c. per lb.. . .The changes in the values of other Agricultural Products are shown in the table of Current Wholesale Prices.

N. Y. Live Stock Markets.—THE CATTLE MARKETS have been freely supplied, the past month, the average receipts being 3,574 per week, which has about equalled the demand during the Lenten season. Prices this week are ½c. higher than our last quotations, or 9c.@9¼c. per lb., estimated dressed weight, for prime; 8c.@8½c. for fair to good; and 7c.@7½c. for poor, with an average of 8c@8¼c. for all sold. None left over at any market during the month.

Veal Calves.—Receipts for the past 4 weeks number 750 per week, which is a large increase from last month. At the last market day (April 15.) with 991 on sale, prices were very low, the best selling at 5c.@5½c. per lb., live weight, and fair veals at 4½c. Many poor ones sold at 3c. and under, not counting the week-old "bobs," which went in lots at 88c.@$1.25 per head.

Sheep and Lambs.—Receipts have only averaged 4,807 per week for the past month, which is less than any previous month for more than a year past. They are now scarce but with an abundance of veal, eggs and fish, prices are lower than last month, though they have ruled high until the last market day, when with over 6,000 on sale, the prices were equivalent to 3½c.@4c. per lb., live weight for clipped sheep, and 5c.@5½c. for unsheared sheep. A few lots of early spring lambs have been sold at $4½@$5 each.

Live Hogs.—Receipts are falling off, the average being 11,620 per week during the past month, which has been ample for the season. Prices have advanced ¼c. Prime, heavy, corn fed hogs are selling at 4½c.@4⅝c., live weight; poor light corn and heavy still fed hogs, 3¾c.@4⅛c. There is a surplus of thin hogs, which sell very slowly.

The Weather.—The Spring has been cold and backward; snow is hardly yet gone from the north sides of the barns and fences, and as far south as this, we had a heavy snow storm as late as April 9. Spring work has consequently been kept back much beyond the average time. The winter grains have not suffered however, and the fruit buds not having come forward to be killed by frost, a large yield of all kinds of fruit is now hoped for. We append notes crowded out last month. OUR DAILY NOTES, condensed, read: *February* 24, rain, high wind with snowfall on 27—*March* 1, 2, clear, fine—3, heavy rain, high wind, barometer 29°20'—4, 1 inch snow—5,6,7, 8,9, fine, mild—10, light rain—11, 12, clear and pleasant—13, light rain—14, heavy rain P.M.—15, rain and snow—16, clear—17, 18, 19, clear, fine—20, rain—21, rainy—22, 23, light snow—24, to 30, clear, fine, spring-like but chilly, with thunder storm on 30th—31, rain——*April* 1, fine, mild—2, light rain—3, 4, pleasant—5, rain—6, 7, pleasant—8, 1½ inch snow at night—9, heavy snow, 4 inches—10 to 16, mainly clear and growing spring like—17, 18, clear and very warm for the date, almost hot; the ground getting dry, and field work going on briskly.

Rain Fall.—The rain and melted snow from Feb. 15th, to March 15th, amounted to 5.27 inches. From March 15th, to April 15th, only 2.79 inches.——The following table prepared at Washington Hights near this city, by Mr. Morris, who keeps the register for the Smithsonian Institute, is quite interesting. It shows the quantity of rain, which has fallen during the past seven years.

Years.	Winter. inches.	Spring. inches.	Summer. inches.	Autumn. inches.	Total inches.
1854–5	12.12	10.09	13.89	11.88	47.98

JOHN P. ADRIANCE,

Manufacturer and Proprietor,

165 Greenwich-st., near Courtlandt-st.,

New-York.

Howard's NEW MOWER and MOWER AND REAPER FOR 1862.

Four sizes—cheap—durable—light draft—free from clogging, and perfect in their operations either in cutting grain or grass.

Send for Circular giving full description and cuts of each machine.

N.B.—I have leased of A. W. Morse the right to use his patented lever or holster, by which the finger-bar of a mowing machine is raised or lowered, therefore farmers will not be subject to prosecution by said Morse in using this valuable invention. Address R. L. HOWARD,

Buffalo, N. Y.

Ingersoll's Cheap Hand Power Presses for Baling

HAY STRAW, COTTON, WOOL, RAGS, MOSS, BROOM CORN, HAIR, HIDES, &c.

These Presses are made for any size or weight of bale required, and delivered on ship board in New-York. Farmers and others wanting such machines are invited to write for Catalogue containing full information.

PRICE OF MACHINES:

No. 1. Press for Hay, &c., weight of bale 150 to 200 lbs., $50.00
No. 2. do. do. do. do. 250 to 300 lbs., 75.00
Rags, Broom Corn, &c., ... 85.00

Weight of No. 1 Press, 800 lbs. No. 2, 1200 lbs.

Over 1000 of these machines are now in use, many of which are extensively used for baling Hay, etc., for the Army. Address INGERSOLL & DOUGHERTY,

GREENPOINT, N. Y.

MILL STONE DRESSING DIAMONDS, Set in Patent Protector and Guide.

For sale by JOHN DICKINSON,

Patentee and Sole Manufacturer, 61 Nassau-st., New-York.

ALSO Manufacturer of GLAZIER'S DIAMONDS.

Rather Grinding.

MR. J. SEDGEBEER, Cincinnati, O.

DEAR SIR:—I am pleased to say for your benefit, and all others who may wish to get one of the best *Iron Feed Mills in the country*, that I have run the Iron Champion Mill I bought of you over two years, without changing the plates, and the mill grinds well yet. I have ground corn and cob, sand-stone, opals, and white marble for plastering, and mixed feed and malt at the rate of forty bushels per hour, and it has given me very great satisfaction.

MARION, O., Jan. 8, 1862. J. K. HAMMERLE.

After the above we feel justified in warranting our mills to grind *any thing*.

Sedgebeer's Conical French Burr Mills, price $120.

Sedgebeer's Patent Champion (Iron) Mills, price $40 & $50.

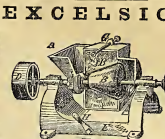
Sedgebeer & Haven's Patent Nonpariel (Iron) Mills, price $40 and $50.

Descriptive Circulars mailed free to all on application.

Cincinnati, O. JAS. L. HAVEN & CO.

EXCELSIOR

BURR STONE FARM MILL,



AND

ANTI-FRICTION

HORSE POWERS.

These machines took TEN FIRST PREMIUMS at Western State Fairs last year, and are justly considered superior to all others. The grinding surfaces of the Mill are BURR STONE, of conical form, so adjusted, that the finest flour or meal, and the coarsest feed may be ground with the same MILL. Any person can operate and keep the mill in perfect grinding order without expense, and it

WILL LAST A LIFE TIME.

Driven by Horse Power our smallest Mill (No. 1) will grind from 8 to 15 bushels of feed the hour; if run by Water or Steam power, 13 to 20 bushels. Price of No. 1 MILL FOR FARM USE, $100. Nos. 2 and 3, MILLS for Millers' use, $140 and $170. The undersigned also make a Wire Bolt for No. 1 Mill, with which Farmers living at a distance from milling establishments are enabled to make their own flour. Price $50 extra.

SHANESVILLE, O., March 13, 1862.

GENTS.—The two mills I purchased are giving perfect satisfaction. I had an experienced miller to test the wheat-mill; the flour is as good, and bakes even better than that we get at the best custom mills.

The No. 1 Feed Mill does its work as well as any flat stone mill could do it, grinds as large a quantity in a given time, and does it with *less than one-half the power* required to run a flat stone mill. N. H. HOCHSTETLER.

GERMAN TOWNSHIP, O., March 13th, 1862.

This is to certify that I have been employed by D. M. N. H. Hochstetler to test the Conical Burr Stone Flouring Mill, bought of Bennet Bros., of New-York, and so far as I have tried it, it makes as good flour as any other mill.

DAVID LAUTENSCHLEGER, Miller

PHILADELPHIA, PA., July 11, 1861.

MESSRS. BENNET BROS.—The No. 2 Mill, driven by a five inch Belt is grinding 50 bushels of Corn per hour. It has proved itself to be what its name purports, "Excelsior."

WM. LEAP, Supt. 15th & Ridge Ave.

THE HORSE-POWER,

FOR DRIVING THRESHING MACHINES, FARM MILLS, HAY CUTTERS, COTTON GINS, CIRCULAR SAWS, MOULDING AND PLANING MACHINES, LATHES, ETC.,

Has proved itself to be the best ever invented. The friction is reduced by IRON BALLS, so arranged in all the bearings, that the whole weight of the castings runs upon them. THREE POUNDS DRAUGHT, at the end of a ten foot lever, will keep the power in motion! thus permitting the ENTIRE STRENGTH of the horses to be used on the machine to be driven. ONE HORSE will do as much work on this power, as TWO on the endless Chain Power. IT IS PORTABLE, and may be used IN THE FIELD as well as in the house. More than TWENTY FIVE PER CENT of horse flesh is saved OVER ANY OTHER POWER IN USE. It is simple in construction, and not liable to get out of order. THE $125 POWER WILL DRIVE ANY THRESHING MACHINE.

Price of Power for 1 to 4 horses.....$125
Price of Power for 4 to 6 horses..... 175

All Goods GUARANTEED, PACKED, and DELIVERED at depot or wharf at above prices.

GENTS.—With two horses on your Anti-friction Power, we drive your No. 1 Mill, grinding *15 bushels of corn per hour*, and cut a large quantity of hay at the same time. I have never seen a power that runs with so little friction, and consequently with so little strain upon the horses.

W. F. COOPER, Supt. 15th & 15th St. *Pass.* R. R. Co., Philadelphia, Pa.

CHATHAM, N. J., Jan. 15, 1862.

BENNET BROS.—I drive my Thresher with two horses, and can do as much work, with as little labor for the horses, as my neighbors can with the same Thresher and four horses. I think one horse will do as much work with the "Anti-friction Power" as can be done with two horses on the Powers used in this neighborhood. Respectfully yours,

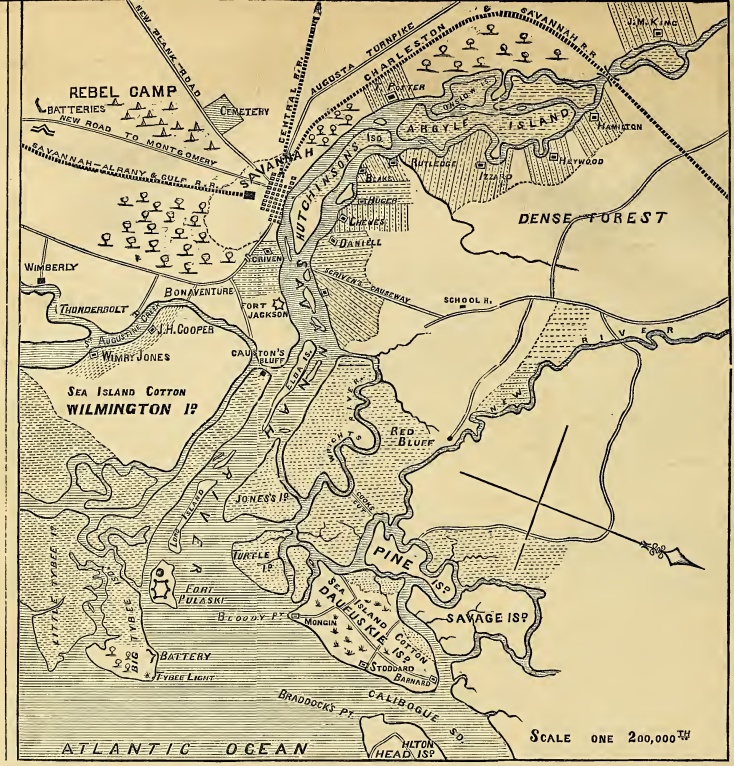
EBN. F. CONDIT.

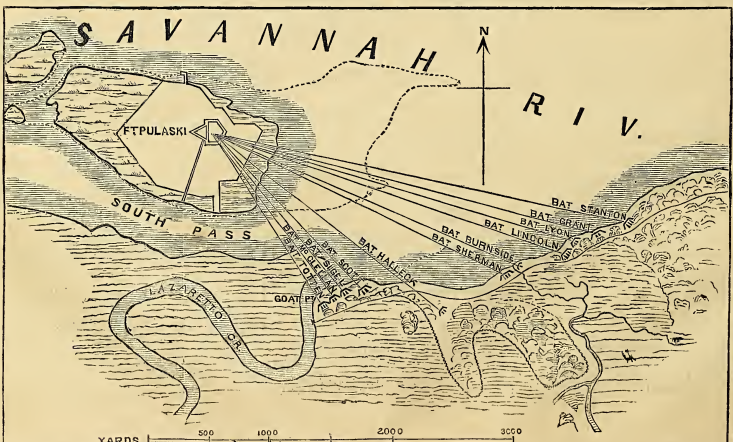
We have completed an arrangement with the Western Transportation Co., by which they agree to deliver our Mills and Powers at ports on Lake Erie at 25 cts. per 100 lbs. Milwaukee, Chicago, and intermediate ports at 20c.* Sheboygan and Green Bay at 35c., and to Two Rivers, Manitowoc, and Port Washington, Wis., at 40c. per 100 lbs.

Agents wanted. State, County, and Shop Rights for sale. Send stamp for Illustrated Circulars to

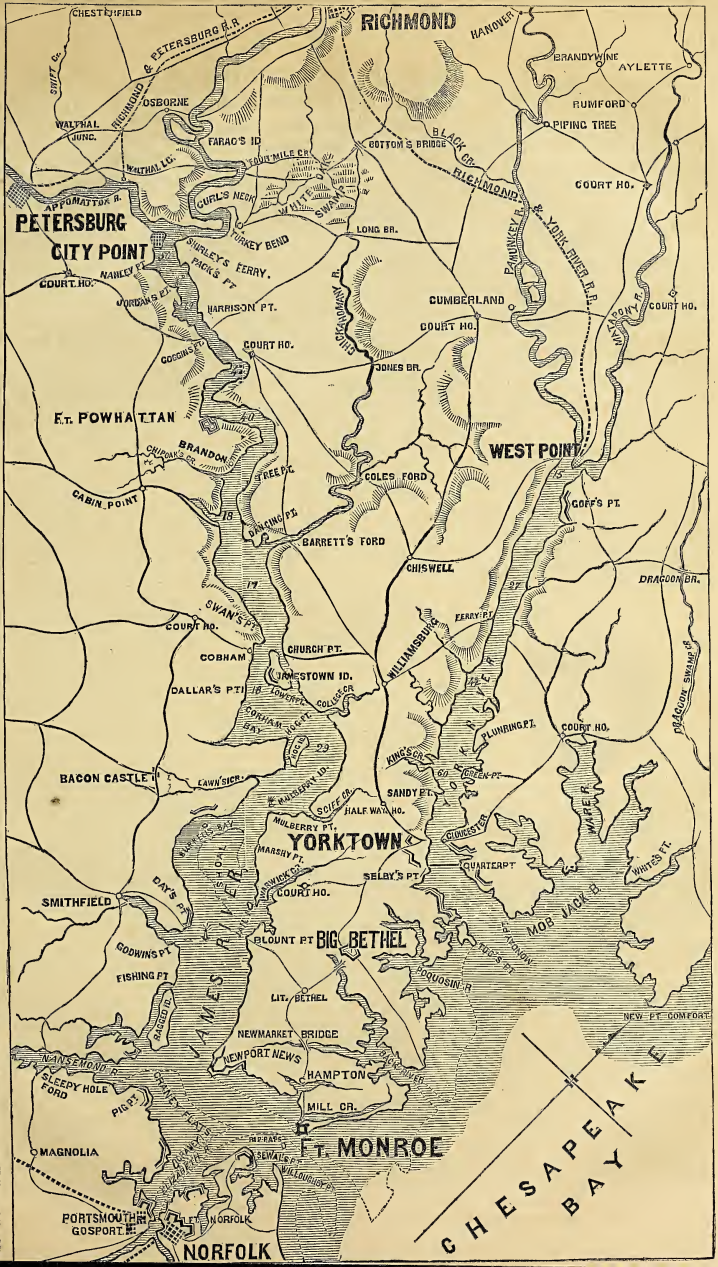
BENNET BROTHERS,

42 and 44 Greene-st., New-York.





The two Maps on this page have a peculiar interest just now. The first shows **Savannah, Geo.**, and its surroundings, including Fort Pulaski which has just fallen. Without doubt the forces under General Hunter and Commodore Dupont are now moving towards Savannah.—The second map shows the plan of attack upon **Fort Pulaski**, which capitulated on *April* 11th. The 11 batteries represented, contained only 36 cannons and mortars, all told. The Fort mounted 47 cannons. This Fort is one of the strongest built in the country, and the fact that its walls were battered down by the recently improved cannons, fired at from one to two miles distance, will revolutionize the whole system of fortifications, throughout the world. The little "Monitor" and the "Merrimac" have destroyed faith in wooden ships. The results of this siege show that iron cased forts, as well as iron plated ships, will hereafter become necessary. We are indeed *making history* in our day



YORKTOWN PENINSULA.—A most important locality is represented in this map. Comparatively few are the families in all our country who have not now a son, brother, father, relative, or at least a friend either in the Valley of the Mississippi, or in the region represented by our map. At Yorktown alone there are now probably over *two hundred thousand* armed men, including both sides. Richmond lies nearly *northward* of Yorktown, and is distant about 35 miles. (The map is on a scale of about 5½ miles to the inch.) To-morrows will be twice memorable in the history of the country. It was the scene of the last great battle of the Revolutionary War (1781.) Whether the final contest of the present war will be there, remains to be seen. That there will soon be a great battle at or near Yorktown, is beyond doubt. We give this map as the locality of one of the great centers of interest, and likely to continue such. The index in the lower corner is a guide to the points of the compass.

The Great American Pump.

Three years unbounded success—prices reduced—the best cistern, tank, spring house, and fire pump. It will not rust, will not freeze; throws 25 feet by hand—raises from all depths, forces to all distances and heights—safe and under tight. Send for drawings and prices to JAMES M. EDNEY, 476½ Broadway, New-York.

RUSSIA OR BASS MATS, SELECTED EXpressly for bedding and tying. GUNNY BAGS, TWINES, HAY ROPES, &c., suitable for nursery purposes, for sale in lots to suit by D. W. MANWARING, Importer, 348 Front-st., New-York.

IMPORTANT NEW SUBSCRIPTION WORK.—Nearly Ready.

THE AMERICAN ANNUAL CYCLOPÆDIA, and Register of Important Events of the year 1862, embracing Political, Civil, Military, and Social affairs, Public Documents, Biography, Statistics, Commerce, Finance, Literature, Science, Agriculture, and Mechanical Industry. Price in cloth $3, in library binding $3.50.

AGENTS WANTED, and exclusive territory given.

There is no work which has appeared in a long time that is likely to command a large share of public patronage at the present critical time, as this. Agents will do well to apply early. D. APPLETON & CO.,

Nos. 443 and 445 Broadway, New-York.

ONION CULTURE.

THIRD (NEW) EDITION.

This work comprises in 32 pages all the particulars for successful Onion Culture, from selection of Seed to Marketing the Crop—being the practical directions given by *seventeen experienced* Onion Growers, residing in different parts of the country. Price 25 cents (or 3 stamps), sent post-paid. Address Publisher of *Agriculturist*.

THE BEST TEXT BOOK.

PROF. ALPHONSO WOOD'S NEW CLASS BOOK OF BOTANY, being outlines of the Structure, Philosophy, and Classification of Plants, with a Flora of the United States and Canada. New and enlarged edition. 8vo pages, 1 vol. 8vo, Price $2. Published by A. S. BARNES & BURR,

51 and 53 John-st., New-York.

$175 REWARD FOR PROCURING THREE hundred paying subscribers to Hall's Journal of Health for 1863. $1 a year. $100 for two hundred subscribers. Do. W. W. HALL, New-York.

LADY AGENTS, $3 a day, at home or to travel for *Mrs. Hawkins' Paper!* Social Games, Etiquette, Arts of Beauty, Curious Pictures, Stories, etc. For specimens and particulars inclose 6 cts. to M. GAUNTT, New-York City.

Great Austin Shaker Seedling.

Specimens of this magnificent berry were exhibited at the office of the *American Agriculturist* last year, measuring six inches in circumference, and weighing one ounce. This monstrous berry is a beautiful scarlet color, and an immense bearer; it is believed that the Great Austin will produce more bushels of fruit to the acre, and is in other variety in cultivation, and will command a much higher price in market than the Triomphe de Gand or Wilson. It bears fruit for a long time, even after all other varieties have ceased; they were sent to New-York market last year up to the 15th of July. We have unbounded the largest stock of genuine plants in cultivation, which we offer at $1 per dozen, $3 per hundred, $20 per thousand; no discount to the trade. The Austin may be safely planted up to the 30th of May. Address either NANCY MILLER, Shaker Village, Amenia, N. Y. or WM. S. CARPENTER, 468 Pearl-st., New-York.

STRAWBERRY PLANTS.

Extra fine, grown with special care, warranted pure, and to give satisfaction. Great Austin or Shaker Seedling, fruits till July 30, $1 per dozen, $3 per 100. Triomphe de Gand, $1.50 per 100. Wilson's Seedlings $1 per 100, less per M.

J. C. THOMPSON,

Tompkinsville, Staten Island, N. Y.

TO ANY ONE IN THE U. S. WHO WILL send us $1 in coin, we will return per same conveyance a package of seeds of the giant Rose Tree Pansy, which seeds germinate readily, and the tree in one of the most highly ornamental in the world. W. W. BRISTOW, P. M., Pleasant Hill, Oregon.

SEEDS—SEEDS—SEEDS.

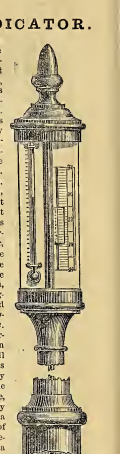
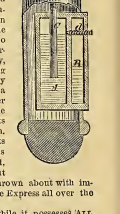
WOODRUFF'S IMPROVED

WEATHER INDICATOR.



While in this age of invention and progress, our American Farmers have seized with avidity almost every invention and implement of husbandry that Art or Science could bring to their aid, one of the most important auxiliaries—the Barometer—has been almost entirely overlooked. This has arisen partly from a want of knowledge of its value and importance, but principally because the peculiar delicacy of construction, and high cost of the instrument have made it unavailable to the masses. In this instrument these objections have been entirely obviated. While its simplicity of construction, and scientific arrangement, render it perfectly portable and accurate, its cost is so low as to place it within the means of all. Indicating with unerring certainty coming changes in the weather, it also affords a simple and accurate medium for measuring heights, while the accompanying Thermometer gives the temperature. The Scientific American, Profs. Williams, Carr, Holmes, Dongan, and a host of public journals and scientific men, recommend it as the *Agricultural Barometer, par excellence*. Profs. Henry, Hackley, Maury, Drs. Arnot and Dick, have computed that an annual saving of five per cent. on all crops, might be made by its use, thus affording an annual saving of over fifty million dollars to the farmers of the United States. It is simple, durable, accurate, perfectly portable, and very cheap; is nicely finished, and affords a very beautiful and ornamental piece of furniture, some of the carved cases being very elegant. We give below a brief description of the principle of its operation.



A, is a glass tube, open at the top, and closed at the bottom by the bulb *B*. *C* is a cistern, filled with mercury, and *D* is a brass scale, graduated to inches and tenths. The tube *A* is filled with mercury, and the scale *D* is attached to the cistern, as shown in the engraving. The mercury in the tube will stand at a height proportioned to the pressure of the atmosphere upon the mercury in the cistern. When the pressure is increased, the mercury is forced up the tube; when the pressure is diminished, the mercury falls in the tube. The scale is graduated to correspond with the height of the mercury in the tube, and the pressure of the atmosphere is indicated by the number of inches and tenths of mercury which it will support.

The cistern, *A*, is of cast iron—cast with two compartments—partly filled with mercury. The tube *C*, filled with mercury, is sealed into the cistern, *A*, and being placed upright, the air is admitted by turning back the screw, *D*, which has a flat place filed in its side near the outer end, where air can pass through the outer wall, when the mercury takes its level, and it is in working condition. To make it portable, turn it upon its side, when the space mercury runs from *B* to *A*, filling tube and cistern, *A*, full—turn in the screw, and it is shut into *A* perfectly solid, and may be thrown about with impunity, or carried by Railroad or Steam Express all over the world in safety.

We claim for this instrument that while it possesses ALL THE INTRINSIC MERIT of other Barometers, it has several peculiar advantages possessed by none of them, while its construction is such as to avoid the objections to which all other instruments are more or less subject. Among its peculiar merits are

1st. Its accuracy, being a Mercurial Cistern Barometer, and constructed on strictly scientific principles. It has stood the severest tests of a great number of scientific men, and is amply recommended by those scientific authorities who had previously discarded and condemned the Aneroid and other ordinary cheap Barometers. For evidence of this we refer to the U. S. Coast Survey, Smithsonian Institute, and other eminent scientific authorities whose certificates we have.

2d. Its cheapness. While possessing intrinsic merits possessed by none other, its price is lower than any other reliable Barometer.

3d. It is perfectly and entirely portable, and can be expressed by stage or railroad to any part of the country with safety. THERE IS NO OTHER PERFECTLY PORTABLE BAROMETER.

4th. Its thorough construction and perfect simplicity makes it the most durable and perfect Barometer ever invented, and renders it impossible to injure or get it out of order, except by gross carelessness or design.

5th. It is unaffected by changes in temperature, which can be said of NO OTHER Barometer.

6th. Its beautiful finish and tasteful design render it a beautiful parlor or library ornament, while it affords a never failing study of interest to the man of leisure, cultivation and refinement, and a sure and reliable indication of the coming weather to all whose interests are affected by atmospheric changes.

BROWN'S BRONCHIAL TROCHES

A Slight Cold, Cough, Hoarseness, or Sore Throat, which might be checked with a simple remedy, if neglected, often terminates seriously. Few are aware of the importance of stopping a Cough or Slight Cold in its first stage; that which in the beginning would yield to a mild remedy, if not attended to, soon attacks the lungs.

Brown's Bronchial Troches were first introduced eleven years ago. It has been proved that they are the best article before the public for Coughs, Colds, Bronchitis, Asthma, Catarrh, the Hacking Cough in Consumption, and numerous affections of the Throat, giving immediate relief.

Public Speakers and Singers, *will find them effectual for clearing and strengthening the voice.*

Sold by all Druggists and Dealers in Medicine, at 25 cents per box.

RHODES' SUPER-PHOSPHATE.
THE STANDARD MANURE.

Manufactured under the supervision of the eminent manufacturing and analytic chemists Robert B. Potts and Frederick Rieth—the sulphuric acid being produced upon a large scale at the works, Camden, New-Jersey.

Guaranteed pure and free from all adulteration.

Dr. Evan Pugh, President Penn. Farm School, in his report upon artificial manures through the Country Gentleman, March 27, 1862, says:

"Rhodes's is the cheapest American Superphosphate, and if Mr. Rhodes will sell super lead guarantee an article to contain 16% or 17 per cent of anhydrous Phosphoric Acid, as combinations soluble in water, (with ten minutes boiling,) his manure would be a very unprofitable investment—a use of the very best Superphosphates manufactured any where in the world, and very much better than any manufactured in this country."

The following report of analyses of one thousand (1000) tons Rhodes' manure, made by Dr. G. A. Liebig, shows even higher results than Dr. Pugh requires:

BALTIMORE, February 28, 1862.

MESSRS. B. M. RHODES & CO.,

Gents:—I have analysed the two samples of Rhodes' Manure, which are averaged from a lot of one thousand tons at the works, and sent to me by Messrs. Potts & Kieth. Sample No. 1 contains of phosphoric acid soluble in water 16.84 per cent, equal to 27.5 of bi-phosphate of lime. Sample No. 2 contains 15.47 per cent, which is equal to 27.10 of bi-phosphate of lime. Both of these samples come fully up to the standard value of your Superphosphate.

Very respectfully, G. A. LIEBIG, Ph. D.

Agriculturists and dealers apply to HENRY E. MORING, General Agent for New-York and New-Jersey,
97 Pearl-st., near Hanover Square, New-York.

PROVIDENCE COMPANY'S CONCENTRATED BONE FERTILIZER.

This is the best Fertilizer, at the price, ever offered to the farmer.

It is composed of pure bone, ground fine, with other materials added to give it greater strength.

It powerfully stimulates the plant from the moment the seed germinates until harvest.

It will not only fill the farmer's crib, but will enrich the soil, Try it.

It is packed in good flour barrels, and delivered to vessel or railroad, in New-York City, free of charge for cartage, at the following prices:

For one barrel, $2; two, $3 50; three, $5; four, $5 50; five, $6; six, $8 50; ten and over, $1 50 per barrel.

Two barrels will manure one acre of corn in the hill.

Send your orders, inclosing the cash, by mail, to

SUPER-PHOSPHATE OF LIME,

Manufactured from **Raw Bones,** dissolved in *Sulphuric Acid,* with a few important additions, at *$10 per ton,* by

A. LISTER & BROTHER, TARRYTOWN, N.Y.

(For results of the past season see *American Agriculturist* for August, 1862, page 234.)

We guarantee every ton of our manufacture to be of uniform quality, and made from pure chemical analysis.

We also manufacture from RAW, (OR UNBURNED), BONES, the fine, medium, and coarse ground **Bone Manure,** for lasting as well as immediate effect on all kinds of farm crops. The coarse ground is particularly valuable for *Fruit Trees* and *Grape Vines,* which require a constant and lasting source of nourishment.

For sale in large and small quantities by

A. LISTER & BROTHER, Tarrytown, N.Y.,
and their agent, P. LANGMAN, 129 Water-st., New-York.

Azotised Wool and Dried Blood
Fertilizer Co.

THIS MANURE by analysis surpasses all others offered in this country, and is infinitely cheaper. Send for circular and price quotes and for the benefit of farmers and cultivators. Send or call for a circular, and see samples.

Chemical Analyses and particular attention given to analyses of soils and plants, at rates available by all.

W. L. ROSE & CO., Agents, 48 Cedar-st., near Broadway, N. Y.

150,000 BARRELS POUDRETTE.

Send your orders early, and you will be sure to get them filled. Address GRIFFING, BROTHER & CO.,
Agricultural and Seed Warehouse,
No. 60 Courtlandt-st., New-York.

PERUVIAN GUANO.—CHAPMAN & VAN WYCK, No. 3 Atlantic-st. (corner of Furman), Brooklyn, N. Y., furnish Peruvian Guano, direct from the government agents, in large and small quantities.

Refer to Barril Brothers, 37 William-st., New-York,
Ex-Gov. John A. King, Jamaica, L. I.

No. 1 Peruvian Guano—Warranted Pure.

Sold at wholesale and retail, at the lowest market price.

Agricultural and Seed Warehouse,
No. 60 Courtlandt-st., New-York.

100,000 Barrels
OF THE
LODI MANUFACTURING COMPANY'S
POUDRETTE,
FOR SALE BY
JAMES T. FOSTER,
No. 66 Cortlandt-st., New-York.

The large facilities which they enjoy by exclusive contract for all the night soil of the City of New-York, and large capital invested in their extensive works, enable them to manufacture an article which is superior to any other fertilizer in market, taking *cost* and *yield* into consideration. It will be sold at the usual price of $1 50 per barrel for seven barrels or over, delivered free in New-York City.

Please take notice that the office and sale of this Company's Poudrette is changed from Messrs. Griffing, Brother & Co., No. 60 Cortlandt-st., to No. 66 CORTLANDT-ST.

Other brands of what purports to be Poudrette are in market, put up in barrels to resemble this. Beware of frauds—buy that only which has the brand of the Lodi Manufacturing Co. Any other article is comparatively worthless.

We call the attention to the following experiences of practical farmers, in different sections of the country:

NORTH PEMBROKE, MASS., Oct. 7, 1861.

James R. Dey, Esq., President of the Lodi Manufacturing Co.:

DEAR SIR—The early autumnal frosts for several years past have seriously injured our corn crops, and rendered it necessary for farmers in this section to seek some fertilizer to give their crops an early start, in order to bring them to maturity in season to avoid that calamity. Having experimented with Guano, Superphosphate of Lime, etc., with indifferent success, in the Spring of 1860 I purchased four barrels of the Lodi Manufacturing Co.'s Poudrette, which I applied principally to my corn crop, with the most satisfactory results. This was the first Poudrette ever introduced into this vicinity. Last Spring I procured from your branch office in Boston about thirty barrels, the most of which I sold to my neighbors, who had witnessed the effect of my last year's trial, which, so far as has been heard from, has given universal satisfaction. To further test the efficacy of your Poudrette, this season I ploughed about two acres of light, sandy soil, which had laid in grass about six years, the last crop of grass being very light. This I planted with corn and applied to each hill about a table spoonful of Poudrette, with no other manure, except a handful or sauce to each hill at the first hoeing. And from present appearances we shall have a better crop than on a field of like soil where we used twenty-five loads of manure to the acre. Its effects on garden vegetables are equally apparent. I am, very respectfully, yours, &c.,

HORACE COLLAMORE.

MERRILL, Mc., Oct. 11, 1861.

Lodi Manufacturing Co.:

SIRS—I bought of your agents, Cross & Newell, two barrels of your Poudrette, and in using the first, I got sick of it and sold the other barrel. But the one that I used I found the principal part on potatoes. I used about half a pint to the hill, and the yield was equal to those plighted on manure at the rate of twenty loads to the acre. My neighbor, who bought the other part of the lot, has bought two barrels more, he would have saved the price of twenty barrels.

Yours, &c., V. B. PAUL.

WALDO, Mc., Oct. 12, 1861.

To the Lodi Manufacturing Co.:

Gentlemen—Last Spring I bought of Cross and Newell one barrel of your Poudrette as an experiment, but with very little faith in its utility. I put it on six rows of corn in different parts of the field, and the same row with barnyard manure, in the usual way—at the second time hoeing. Where I put the Poudrette the corn was twice the height of the rest of the field, and the row is one-third heavier, and has ripened about eight days earlier. I think it the very thing we want for shelling corn in this country, and shall use it more extensively another year.

Yours, &c.,
WELLINGTON MOOREY.

SMYRNA, Del., Oct. 1, 1861.

Gentlemen—I had heard of the Poudrette manufactured by the Lodi Manufacturing Co., and thought I would try a small quantity on a lot of land intended for corn, and as I could not get it nearer than Philadelphia, I went and bought of the agent, twenty barrels, and applied two barrels to the acre, dropping the corn and a handful of Poudrette to each hill. I left out a part of two rows, and put no Poudrette, to ascertain if there was any value in it, and noticed those two rows during the season; and where the Poudrette was used, the corn was decidedly the best, and I have no hesitation in saying it is a good manure. I shall use more of it made from one-third to one-half more by using it.

Yours, respectfully, JOHN G. BLACK.

CHESTER, Pa., Sept. 15, 1861.

To the Lodi Manufacturing Co.:

Gentlemen—I purchased this season of Messrs. Baker & Co., eleven barrels of Poudrette and one keg of Plumbe, which I put on my corn. I marked the place where I put the Plumbe, which, when started, looked well, but now the corn where the Poudrette was on is much the best. Last year I used Allen & Goodrich's new Fertilizer, which did no good at all, as the corn done better without the manure. I think the Poudrette made by your Company the cheapest manure in use.

Yours, &c., A. R. PERKINS.

The Company's pamphlet, containing directions for its use, with other valuable information and the experience of over one hundred farmers, will be sent free to any one applying for the same. Address,

JAMES T. FOSTER,
Care of Lodi Manufacturing Company,
66 Cortlandt-st., N. Y

Strawberry Show

AT THE

OFFICE OF THE AGRICULTURIST,

41 PARK ROW (TIMES BUILDING,) NEW-YORK.

$50 IN PRIZES.

The Proprietor of the *Agriculturist* invites Strawberry Raisers, of this vicinity and elsewhere, to make an exhibition of their choice fruit on Friday and Saturday, June 20th and 21st,* in the spacious Office of the *American Agriculturist*; and to give zest to the exhibition, offers the following

PRIZES:

For the largest number of most approved varieties, (one quart each)..... $10
Second Prize..... 5
Third Prize..... 3
For the best dish of market berries, (two quarts of one variety.—It will be very desirable to show plants with fruit, in addition)..... 5
For the best dish of the best berries for general cultivation, (two quarts one variety)..... 5
For second and third best..... $3, $2
For the largest three berries of one variety, (weight and size both being considered)..... 3
For the best New Seedling..... 3
For the best quart of White Strawberries..... 2
For the best flavored Strawberries (one quart)..... 2
For the best quart Triomphe de Gand..... 1
For the best quart Wilson's Albany..... 1
For the best quart Hooker..... 1
For the best quart Dewey's Seedling..... 1
For the best quart Victoria..... 1
For the best quart Jenny Lind..... 1
For the best quart Vicomtesse Hericart de Thury... 1

The berries to come in competition for the premiums must be upon the tables as early as 10 A. M. on Friday, June 20th,* and each specimen must be correctly labeled. The Awarding Committee will attend to their duties at 11 A. M.—at which hour the exhibition will open. When the premiums are awarded, the *names, places of residence* and of *business* of the exhibitors will be placed upon the specimens, and the prize samples designated.

The fruit will be subject to the order of the exhibitors at 4 P. M., Saturday, 21st.

* Should any peculiarity of the season require a change to be made in the date of holding the exhibition, notice will be given in the June *Agriculturist*.

An American Exhibition

OF

Pumpkins, Squashes, and Ornamental Gourds.

There will be a Public Exhibition of **Pumpkins, Squashes, and Ornamental Gourds,** at the office of the *American Agriculturist*, 41 Park Row, New York City, opening on Wednesday, Nov. 5th, 1862, at which the following prizes will be paid by the Publisher, upon the award of competent Committees.

CASH PREMIUMS.

I. For the *Heaviest* Pumpkin or Squash... $20.00
II. For the 2nd do. do. ... 10.00
III. For the 3d do. do. ... 5.00
IV. For the Best do. do. for cooking.. 10.00
V. For the 2nd Best do. do. ... 5.00
VI. For the largest yield on a single Vine.*... 10.00
VII. For the Best do. do. *... 5.00
VIII. For the largest and finest collection of Fancy or Ornamental Gourds*..... 10.00
IX. For the 2nd do. do. *... 5.00

* All to be grown by one person and to be accompanied by an affirmed statement from the grower, and two disinterested persons who assist in gathering.

Note 1.—The specimens receiving the Prizes will remain on Public Exhibition at the pleasure of the Publisher who offers the prizes. The other specimens will be subject to the order of the exhibitors, or be sold at Auction or otherwise disposed of, for their benefit.

Note 2.—All Exhibitors must notify us of their intentions by Oct. 10th, and deliver specimens for competition on or before Nov. 3d. Specimens to be delivered free of charge.

Premiums for Northern Grown Cotton.

One Hundred Dollars are offered for the best five specimens of cotton grown above latitudes 38° and 40°, this year. See particulars in February *Agriculturist*, page 64.

American Agriculturist in German.

The AMERICAN AGRICULTURIST is published in both the English and German Languages. Both Editions are of the same size, and contain, as nearly as possible, the same Articles and Illustrations. The German Edition is furnished at the same rates as the English, singly or in clubs. A club may be part English, and part German.

EXTRA PREMIUMS,

Only to May 10, 1862,

(And at no other time.)

STRAWBERRY PLANTS

Sent Free by Mail.

CONDITIONS:

I. To any person forwarding, now or before May 10th, ONE subscriber to the *American Agriculturist*, at $1 a-year, (*to begin Jan. 1st, 1863.*) we will present (if desired) **Ten Plants of the Triomphe de Gand Strawberry,** forwarded free. These plants set in good soil early this Spring, will multiply greatly the present season, and furnish plants enough to start a large plot in August, for fruiting next year.

II. To any person forwarding, after April 1, and before May 10, TWO subscribers to the *American Agriculturist*, at $1 each, (for the year 1863,) we will send (if desired) **Twenty-five Plants of the Triomphe de Gand Strawberry,** to be forwarded free as above.

III. To any person forwarding, now or before May 10th, THREE OR MORE subscribers for the present year, (from Jan. 1,) at $1 each, we will present, **for each name, Fifteen Plants** of the **Triomphe de Gand Strawberry,** to be forwarded free as above.—N. B. When three or more names are sent together, the recipient may order, if desired, one-fourth of the plants to be the BARTLETT STRAWBERRY, a new and very promising variety.

N. B.—Three days before sending out the above plants, a printed slip or circular will be mailed to each person entitled to receive them, notifying him of the day on which the plants will be mailed, so that they can be looked for on their arrival. The printed slip will also contain directions for treatment of plants, soil, culture, etc.

(For other particulars see last month.)

Bound Volumes—Binding—Covers.

We have complete sets of Vols. 16, 17, 18, 19, and 20, both unbound, and bound separately, in neat covers with gilt-lettered backs.

PRICES AT THE OFFICE.

Volumes 16, 17, 18, 19, and 20, *unbound*..... $1.00 each.
Volumes 16, 17, 18, 19, and 20, *bound*..... $1.50 each.

PRICES WHEN SENT POST-PAID BY MAIL.
(They can not go unpaid.)

Volumes 16, 17, 18, 19, or 20, *unbound*..... $1.13 each.
Volumes 16, 17, 18, 19, or 20, *bound*..... $2.00 each.

BINDING.—Sets of numbers brought to the office will be bound up neatly (in our regular style of binding the *Agriculturist*) for 50 cents a volume.

PREPAIRED COVERS.—Covers for binding, neatly made, with title, etc., gilt upon the back, ready for the insertion of the sheets by any bookbinder, can be furnished for Vols. 12, to 20 inclusive, at 25 cents per cover. *Covers can not go by mail.*

American Agriculturist.

For the Farm, Garden, and Household.

A THOROUGH-GOING, RELIABLE, and PRACTICAL Journal, devoted to the different departments of SOIL CULTURE—such as growing FIELD CROPS; ORCHARD and GARDEN FRUITS; GARDEN VEGETABLES and FLOWERS; TREES, SHRUBS, and FLOWERS for the LAWN or YARD; care of DOMESTIC ANIMALS, &c., &c., and to HOUSEHOLD LABORS. It has also an interesting and instructive department for CHILDREN and YOUTH.

A full CALENDAR OF OPERATIONS every month.

THREE to FOUR HUNDRED, or more, illustrative ENGRAVINGS appear in each volume.

Over TWELVE HUNDRED PLAIN, PRACTICAL, instructive articles and useful items, are given every year.

The Editorial Contributors are all PRACTICAL WORKING MEN.

The teachings of the AGRICULTURIST *are confined to no State or Territory, but are adapted to the wants of all sections of the country—it is, as its name indicates, for the whole* AMERICAN CONTINENT.

TERMS—INVARIABLY IN ADVANCE,
(For either the English or German Edition.)

One copy, one year..... $1 00
Six copies, one year..... 5 00
Ten or more copies one year..... 80 cents each.

☞ Add to the above rates: Postage to Canada, 6 cents, to England and France, 24 cents; to Germany, 36 cents.

Postage anywhere in the United States and Territories must be paid by the subscriber, and is *only six cents a year*, if paid in advance at the office where received.

All business and other communications should be addressed to the Editor and Proprietor,

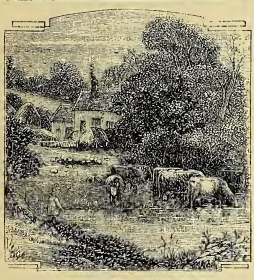
VOLUME XXI—No. 6. NEW-YORK, JUNE, 1862. NEW SERIES—No. 185.

Entered according to act of Congress in the year 1862, by ORANGE JUDD, in the Clerk's Office of the District Court of the United States for the Southern District of New-York. ☞ Other Journals are invited to copy desirable articles freely, *if* each article be credited to *American Agriculturist.*



June.

"Amid his subjects safe,
Slumbers the monarch swain; his careless arm
Thrown round his head, on downy moss sustained;
Here laid his scrip, with wholesome viands filled;
There, listening every noise, his watchful dog,
Sight fly his slumbers, if perchance a flight
Of angry gad-flies fasten on the herd,
That startling scatters from the shallow brook,
In search of lavish stream.—THOMSON."

Of all months of the year, commend us to June for sight seeing and enjoyment. The poet's picture is in keeping with the month—the bank of a placid stream half guarded by woodland and half by meadow, the farmer taking his noon-day rest, the herd, the dog, and the speckled trout that we only think of under the bank. Nature is never so fresh and beautiful as now; the leaves that have lingered so long in buds, have burst all their encasements and are expanded to their full size. How delicate and glossy they are! How rapidly the wood is making! You can almost see the process of growth. Beneath your feet, the grasses are springing in the greatest luxuriance, and some are already waving their little plumes and tassels in the air. The endless verdure is relieved by the blooming dandelions, and buttercups.

And the mouths for which Nature has made ready this abundant supply, are here to be filled. The peaceful kine are grazing quietly in the meadow. They stop a moment to stare at you with their large liquid eyes, but only a moment, for they go to grass without any bidding, and will not rest until their maw is filled, and the noon-tide heat drives them to shelter. They make music as they move on slowly in column, plucking the grass like a band of reapers. When chewing the cud in the shade, with half closed eyes, they make another familiar sound suggestive of the fullest animal content. It is an anodyne for fretted nerves, to see them thus tranquil.

Yonder, upon the distant hill-side, you see the flocks of sheep and the young cattle that do not need to be brought home at night. They are a beautiful sight, with their lambs which are now nearly large enough to be separated from their mothers. They are not the less beautiful in the eyes of the farmer that they are turning the grass into money with very little of his labor or supervision. It is one of the delights of June that the days are so clear that you can see distant objects with the greatest distinctness. The clouds are brought down to you, and the far off hills and mountains become your neighbors. But the creatures that help man are by no means confined to his domestic animals. Here in the orchard are a multitude of birds, robins, blue-birds, woodpeckers, sparrows, and wrens, all busy helping him. They make money without thinking of it. Watch that pair of robins as they tend their young. First the mother comes with earth worms or caterpillars that she has plucked from the apple-trees. The little birds know the sound of her wings, and their mouths open with a murmur of delight as soon as she alights upon the nest. The worms are dropped into their mouths. She is hardly gone before her mate comes with his bill full of insects and thus the whole day is spent in catering for their young. Hundreds of noxious insects are thus destroyed each day, by every family of robins. The appetite of the young for animal food is astonishing. There seems to be no limit to their capacity to devour, save the capacity of the birds to bring supplies. Where insects are abundant, the growth of the young is very rapid; in a few weeks from hatching they are on the wing, apparently as large as old birds.

But we have some insects that hide under the bark, and burrow in the wood, doing their mischief out of sight of human eyes. The woodpecker is the artist to attend to these sly depredators. Murder is said to be one of the fine arts. It is, in the hands, or rather in the bill of the woodpecker. He perches in the top of an old tree, with his buoyant chivalric song, bidding all his fortified enemies "Wake up, Wake up," as if he would not surprise them, or take any advantage of their somnolency. He is in no hurry for slaughter. He hops along the limbs, scans the underside closely where the holes are most likely to be found. He knocks gently on the limb near the premises of the grub as if he expected a cordial invitation to come in. He stops to listen as if he would find out whether his gentle knock has waked up any body. Possibly he hears a gnawing inside as if his neighbor was retreating at the back door. He works sharp now and the bill is driven into the decayed wood with strokes so rapid that you can not count them. The chips fly, and the artist waxes warm over his work. At length he strikes his enemy, and with his long bill drags him from his hole and bears him off in triumph to the knot-hole cabin that you see in yonder tree. His young family have a feast, and another of the farmer's enemies is disposed of.

Listen again: here is another sound in the orchard. The apple trees are full of blossoms, and almost as full of bees, and the murmur of their myriad wings falls on the ear with a soothing melody. Their legs are covered with the yellow dust, suggestive of the price of their luscious stores. All the air between the orchard and the hives is a busy highway for these little laborers. They preach industry to man while they fill their hives with honey. There is a charm in apple blossoms, and bee-music is none the less pleasant to the farmer because they bring him money.

And now that we have taken it upon us to look up the humble helpers of the farm, we must say a good word in behalf of that much abused animal, the *Mephitis Americana.* You think at once of his bad name, of the eggs he has stolen, of the setting hens and turkeys he has broken up, of the roosts he has invaded, and the breezes he has polluted. Mr. Skunk is guilty of some misdemeanors, as all useful animals are. The eat catches your chickens, the dog runs mad and destroys man and beast with his virus, the horse runs away, smashes the carriage, and breaks your bones, the cow breaks down the shrubbery with her wicked horns, and the hogs get into the corn. They are all very good creatures in their place, not so good out of it. The same can be said of our hero. Possibly the hen-roost might have been made proof against vermin, and the fowls might have been confined to a yard—to your profit as well as to the safety of the eggs. If the eggs were out of place, the wandering animal whose instinct prompts him to eat eggs, wherever he finds them, is hardly so much to blame as the owner of the eggs. The eggs which you leave at loose ends are only a fair compensation for his services. All summer long he roams your pastures at night, picking up beetles and grubs, poking with his nose potato hills where many worms are at work. He is after the grubs, not the tubers. He takes possession of the apartments of the woodchuck, who has quartered himself and family upon your clover field or garden, and makes short work with all the domestic arrangements of that unmitigated nuisance. With this white backed sentinel around, you can grow clover in peace, and the young turnips will flourish. Your beans will not be prematurely snapped, and your garden sauce will be safe from other vermin. The most careless observation of his habits shows that he lives almost exclusively upon insects. While you sleep he is busy doing your work, helping to destroy your enemies. In any fair account kept with him the balance must be struck in his favor. Thus among the animals we often find friends under the most unpromising appearances, and badly abused men are not unfrequently the benefactors of society.

Calendar of Operations for June, 1862.

[A glance over notes like the following will generally call to mind some piece of work that would otherwise be forgotten or neglected. The remarks are more especially adapted to places between 38° to 42°; but will be equally applicable further North and South, by allowing for latitude.]

Farm.

Tillage is the great work of this month. If a man is skeptical of Jethro Tull's philosophy, he can dissipate his doubts by stirring the soil early and late. Cultivate, harrow, hoe, plow, and by all methods, stir and comminute the soil. This allows the air free access to all the surface particles, saves every drop of dew and rain, and puts the growing crops upon their best behavior. It subdues the weeds, exterminates foul seeds, and cleans the land for future crops. It is a substitute for manure, and at the same time makes the most of the manure that is put into the soil. From twenty to thirty per cent can be added to the corn crop by good frequent tillage alone. Just what the philosophy of this result is, perhaps none of us can tell. The fact is very well attested. Do all the tillage possible with the horse or mule. Hand hoeing is expensive. If corn is in row both ways, nearly all the work can be done with the cultivator. It is not yet too late to supply missing hills of corn.

Barley is better sown early, but is less injured by late sowing, than oats. It succeeds best on a deep gravelly loam, well worked and free from weeds. It properly follows corn or any hoed crop. Plow the land, then harrow to leave it level, and after sowing the seed harrow and bush. Sow three bushels to the acre. Some sow four bushels and claim that it pays.

Barns and Sheds should be put in order for the hay and grain crops which will soon be ready for harvest. Take time by the forelock, clean out all foul stuff from the bottom of bays and mows, and put the scaffolding in order. If hay is mixed with weeds and sorrel do not save the mow seed, as so many are in the habit of doing.

Barn Yards—Cover the bottom with muck or loam and plow or harrow the droppings into it once a month. If there is any bad odor about the yard you are losing money. Composting with the plow is cheap.

Beans—Plant early where corn has failed, and in soil wholly devoted to them. They do better on light land than most other crops, and are very profitable both for the family and for the market. Plant the best smaller varieties. There is a difference of one half in the price of the poorest and best field beans. Plant abundantly.

Beets—Mangel wurzel and sugar varieties sown early this month, will have plenty of time to mature for winter feeding. They save hay and grain, not only in feeding cattle, but pigs. Sugar beets make swine thrive, along in the early fall. Have a full supply for them.

Butter, if well made and packed during this month, will keep throughout the year. Cleanliness and thorough working are the two essential points to be observed. The milk room should be well ventilated, cool, and free from dust, insects, and offensive smells. Experiment to learn if this be true; note also the quality of the butter. In sending butter to market, have the cask or pail look neat and inviting, and plainly marked. New tubs should be well scalded with buttermilk and brine before packing, to remove the flavor of the wood.

Cabbages—Plant out for late crops. Hoe and cultivate between the rows of those previously set, *at least* once a week—the oftener the better. Set plants between the rows of early potatoes, which are to be dug about the first of July. Examine often to destroy cut worms and other insects. A farmer can not well have too many cabbages. They can be kept until May as well as a potato, and are cheap, succulent food for cattle, pigs, and poultry, all through the winter.

Carrots—Sow both as a general crop and as a succession to onions and early potatoes. The sooner they are sown the better. If the soil is deep and rich, sow fourteen inches apart for hand cultivation, and only four inches for horse cultivation. They may be sowed between the rows, to succeed onions; leave every third space vacant to afford room for curing the onions when pulled.

Cheese—Try to improve the quality, rather than to increase the quantity. "White-oak" cheeses are always a drug in market, while those of first quality are always in demand at good prices. See communication on page 182.

Cattle—Young cattle, especially calves of the present season, need attention to keep them growing. Allow them the best pasture. Remember the first year of an animal is the most important. Good cows and oxen do not come from stinted calves. Keep them out of the road.

Corn—A good crop of the R. I. Premium, Canada Yellow, the true Dutton, or the King Philip, may be obtained, if planted during the first week of June. Indeed, most kinds of corn, (except the very large sorts which require a long season for maturing,) may be planted at this time. Some good farmers do all their planting as late as June 1st, soaking and tarring the seed, rolling in plaster, and manuring in the hill with compost manure, superphosphate, or Peruvian guano mixed with plenty of soil. Go through land already planted, with the cultivator and hoe, clear out all weeds and grass, thin the corn to four stalks in the hill, and replant missing hills. Sow and drill both the dent (tooth-shaped) and the sweet varieties for cutting green in August and September. In land troubled by moles, run the plow through both ways as soon as the corn is up, and as often as their runs are established.

Grain Fields will whiten to the harvest in southern localities. Wheat or rye should be cut as soon as the berry is advanced enough to bear moderate pressure of the thumb-nail, without breaking, or just after it leaves the "milk." Examine the fields for the earliest and best portions, to be left to ripen fully for seed. Save no grain for seed from weedy fields. Much of the profit as well as pleasure of farming depends upon clean seed, which makes clean fields.

Haying will begin in the early situations and well drained and manured fields. Cut grass or clover for hay, just as the bloom is passing away, and the seed commences to form. If left later, much of the nourishing part of the stalk is lost in the woody fiber. (See article on Hay Caps, page 173.) Hay Caps will enable you to cure much of the hay in the cock, which will give a better quality of fodder. Mowing machines and horse pitchforks will pay on all farms, where there is much grass to cut.

Manure—Turn every source to a account, as recommended in previous numbers. Take a wheelbarrow from the garden, etc., into the pig sty, and su ply the swine with plenty of material, to work over at their leisure. Deal largely in peat and muck, or loam and sods in their absence, during this month. Decomposition goes on rapidly in hot weather. Better pay double price for help than to have your yard and sheds bare. Manure is the sheet-anchor of good farming.

Millet is one of the best forage plants, well adapted to soiling. Sow any time this month, best before the middle.

Peas—Sow or plant at once. They make excellent food for swine, when fed green with the straw, or ripened and ground with the cob, or when fed alone, cooked or soaked. Hogs will grow and fatten well on peas, but need corn to finish off upon.

Potatoes—Keep well hoed until blossoming. Hill moderately, or not at all. Top-dress with ashes and plaster.

Poultry—Compel them to lay in their appropriate places, by confining them in the poultry yard until after noon. Allow none to sit after the middle of this month. Meanwhile whitewash their apartments monthly, and use the fresh droppings mixed with plaster in the garden, and to make liquid manure.

Rutabagas and Rock turnips should be sown or transplanted from the 20th to the last of the month for field culture, if designed for cattle. Plant in drills two feet to thirty inches apart. Young plants of these varieties are as easily transplanted as a cabbage. They make a good succession crop to early potatoes. Manure with bone-dust, superphosphate, or Peruvian guano.

Sheep washing and shearing demands the attention of the farmer with the first settled warm weather. Read article in May number, *Secular Cut*. Mark each sheep plainly as soon as sheared, and designate ewes having superior fleeces, with a special mark, that they may be reserved for breeding. Dock and castrate lambs, if not already done, and guard against the fly by smearing wounds with tar. Look to the foot rot. See article on Labelling p. 173.

Sorghum—Drill or sow broadcast for cutting and feeding green, or to be cured for winter fodder.

Sugar beets and Mangels—Sow first week if possible or before the 20th, in mellow, rich ground; drills 2 feet to 30 inches apart, or the rows in pairs a foot apart and 3 feet between the pairs of rows—for convenience in cultivating. The plants should finally stand 8 inches apart.

Swine—Keep them growing with whey and milk from the dairy, mixed with ground feed. Give them the range of the orchard, to destroy grubs and worms in unsound fruit. A good clover pasture will afford them excellent feed. Give them plenty of pure water.

Tanners' Bark—Peel from hemlock and oak, as soon as it will "run" freely, and pile it when partially dry, so as to protect from rain.

Tobacco.—Prepare the ground for receiving the plants and transplant them, if possible, on some rainy day about the 15th, at any rate before the 25th. (See article on p. 168.

Tools, particularly for haying and harvesting, should all be in readiness before the season of use.

Weeds grow rapidly and soon produce seed, if left during this month. Thistles should be persistently cut with the spud below the surface. Lizards or Snapdragon may be *smothered* by sea-weed or swamp hay. Clean tillage *pays*.

Orchard and Nursery.

If the orchard has been well attented to in former years, it will require little care now. The caterpillar nests should be pulled down as fast as they appear. This can be done by running a pole with one end split into the nest, twisting it until it is completely torn from the branches. Select early morning or wet weather when the occupants are at home, to demolish their houses—and themselves.

The middle and latter part of June is a good time for the general pruning as heretofore advised. The wounds now made harden well, and the new wood immediately begins to cover them. Look to the young trees particularly, and see what shape they would assume, and whether the branches would be too crowded when fully grown if all the limbs are suffered to remain. An open head is particularly desirable, and to this end quite likely a portion of the inner cross branches will need cutting out with the pruning knife, and head them back if running up too strong, or some of the outer limbs are pushing out of symmetry. A vacancy on one side of the tree can soon be supplied by cutting the adjacent branches to buds upon the side to be filled. If the old orchard has been neglected and it is desirable to remove large branches, they should be taken off with a fine saw close to the trunk of the tree, or other limbs. It is also advisable to coat the sawed space with a solution of gum shellac, dissolved in alcohol to the consistence of thin molasses, putting it on with a camel's hair brush. By all means, spare time enough to give the orchard its annual pruning now—it will abundantly pay. After a little practice, a glance will tell what branches should be removed, to form a well balanced, tolerably compact head, with few inside crossing limbs. Two extremes should be avoided. One is, the cutting out of all the central shoots, and encouraging a tall or wide-spread growth. This leaves the bearing portions high in air, where they are swayed and thrashed by high winds, with a long distance for the fruit to fall; it is also inconvenient to pick. The branches are often so spread with the weights upon their extremities, as to split them down. Again, with the pear especially, there is not sufficient shade upon the main branches and body of the tree. The other extreme is, heading back too strongly, and not cutting out the center sufficiently. We have seen the branches so thick and interwoven, that it was almost impossible for fruit to grow, or to gather it.

Stimulate the growth of both old and young trees in a poor soil, by a liberal coating of manure about the roots. Remember that new wood and fruit spurs are wanted this year, to bear next season. Shortening-in in June checks the flow of sap, and tends to the formation of fruit buds. A stout cord or strap, fastened around the body of a young tree, or the main branches of older ones, tends to the same end, by compressing the sap vessels, though this is not generally advisable, except in the case of persistent non-bearing trees.

Look to the grafts set early in spring and renew the wax or clay where needed. Rub off the natural suckers.

The borer-moth will soon be at work, laying eggs about the base of the apple, pear, peach and quince trees. Keep everything clean about the trees that no protection be afforded either to the millers depositing the eggs, or to the eggs themselves. A newspaper tied around the tree, close to the ground, or for one foot or more above, will usually save the trees. If fearful that eggs are already there, wash the body with strong soap suds, or potash and water. The same wash will remove scale or "lice," which are now quite small, and easily rubbed off. See article on destroying insects on pages 141 and 177.

Evergreens may well be transplanted early in June. Besides attending to this in the nursery, let the newly planted and exposed orchard have a belt set upon the sides most affected by the prevailing winds, as advised last month. A mulch of straw, or fresh cut grass, spread about the roots of newly planted trees, will keep the ground moist in dry weather. A frequent application of *hoe* will serve a similar purpose. By no means allow a mat of grass or weeds to grow around young trees. The horse and hand hoe should also be kept at work in the nursery to lighten the soil and keep down weeds.

Kitchen and Fruit Garden.

The excellence of most table vegetables is in proportion to the *rapidity* of their growth. However, too great forcing sometimes throws the growth into tops and leaves rather than into the roots, but the two generally bear a close relation to each other, if the seed is good. There are a few general principles which every gardener should bear in mind. Do any hand weeding, but neither hoe nor stir the soil in wet weather. The drier the weather, the more beneficial is it to stir the surface, provided the rootlets be not touched. Liquid manure must be used with extreme caution in dry weather, and its effects are much more noticeable in showery times. Watering once commenced must be continued—watering the *plant* is of

little avail, but it is the *soil* which should be moistened all about the plant, and that too below the surface.

Asparagus may be injured by too long and too close cutting; when green peas and string beans come, let it grow. It should not be cut much after mid-summer, (June 20th)

Beans may be planted any time during the month, but it is desirable not to delay much after the first; even Limas will do well when planted the first week in June, if they have frequent hoeing and liquid manure.

Beets—Sow long blood, and blood turnip, in mellow soil before the 20th, for fall and winter use. A handy way to sow beets or mangels on a large scale is to make a wheel of a two inch plank and insert pins 6 inches apart, to mark inch-deep holes in rows; put two seeds in each hole and cover by hand. Thin and hoe as soon as the rows show.

Cabbages, Cauliflowers and all the family may be transplanted any time during the month, for Autumn use.

Carrots sown now will make a good crop.

Celery—Sow for winter crop, and prick out young plants to have a good supply of well grown stocky ones for transplanting in July. For fall crop, transplant about the middle or last of the month, in trenches 4 feet apart, a foot deep and well manured and mellow.

Corn—Continue to plant for succession, until July 4th; plant none but the sweetest. Hoe frequently.

Cucumbers, Melons, and Squashes—Put in cucumbers for pickles any time during this month. Remove gauze frames before the plants crowd them. Occasional watering with liquid manure, made by mixing fresh cow droppings, or hen manure with water, will repel insects, and rapidly forward the growth; dust with ashes and plaster or lime. The striped bugs may be easily taken early in the morning, while the dew is on, and destroyed. Examine the under side of the squash leaves for eggs of the squash bug; hundreds may be killed before hatching.

Egg Plants—Transplant into good soil abundantly enriched, best with horse manure; hoe and water frequently.

Insects—June is the month in which they do the garden most damage, and constant vigilance is the price of freedom from their depredations. Whale-oil soap, very dilute, and successive flocks of young chickens or turkeys, to be removed as soon as they begin to do any damage, are the best preventives.

Lettuce—Few varieties do well after mid-summer. The Tennisball and Curled Silesian grow as well as any. Sow or transplant into partial shade, and water frequently.

Onions—It is important to force a quick development, hence direct seed onions to three or four inches and stir often. Potato onions (the best for the family table,) may be planted as late as the first week in June, eight to ten inches apart. For pickles sow rather thickly in poor soil.

Parsneps may be sown early this month; keep the surface mellow; they enjoy liquid manure.

Peas—Sow for late Summer use and for seed. They will not be troubled by bugs if sowed after mid-summer.

Potatoes—Late plantings often do very well, escaping rot when early ones suffer, but the reverse is oftener true.

Radishes—Sow spring varieties among other crops where they will be partially shaded. Winter varieties, (Black Spanish, Late Brown, etc.,) last of the month for use in August. Leave some of the early crop for seed—and for seed pods to be used for pickles.

Rhubarb—Cut up and dry or bottle a good supply for winter use. Let no seed stalks run up.

Tomatoes—Transplant for main crop; use a broad shingle or two to protect from the sun at first, and after a day or two, shift it so as to reflect the heat upon the plant. Hoe frequently, and pinch in some of the leading branches to give a bushy habit and earlier fruit. Hang the vines over poles slightly inclined, to keep the fruit from the ground and to give them air.

Turnips—Sprinkle with plaster when the dew is on to drive off the ground flea.

Weeds which come from seed are easily killed and there is no excuse for the gardener who allows them to be seen, any more than there is for a boy with a dirty face. Those from subterranean roots are more difficult to get rid of, but faithfulness will in time do the work.

Vacant Spots—No good gardener has any. There is almost always something which may profitably occupy them; if not, sow oats or rye, on even very small spots, and spade it in when you want to use the plot.

SMALL FRUITS.

Blackberries and Raspberries—Keep all canes, including new growth, properly tied to stakes or trellises. Allow only those new shoots to remain, which are wanted for next year's bearing, unless they are needed to make new plots. If specimens of large fruit are desired, thin the clusters and berries, leaving only one or two clusters on a cane, and water freely during dry spells.

Currants—Keep the bushes in good form by pinching in to short spurs: this will save the necessity of further pruning, except to remove dead wood. Keep the ground around them loose, and free from weeds. Water the bushes with soap suds, and other wash from the house. Pick the fruit for jelly as soon as ripe; for wine-making, now much practised, it is better fully matured.

Fruit Trees—Keep dwarf pears and other fruit trees trained to good shape, by pinching out superfluous shoots as they appear, and checking the production of much wood. Trees transplanted this year, or last fall, should not be allowed to mature any fruit unless their growth is very vigorous. If cherries can not be marketed, preserve them in bottles, or remove pits and dry them.

Gooseberries—Keep the surface of the ground moist by frequent stirring, mulching or loose stones.

Grapes—Proper care in pinching out unnecessary shoots, and shortening in too rampant growth, will obviate the necessity for severe cutting in the fall, and the strength of the vine will be retained in the remaining canes. Continue to watch against insects, and mildew. For the former, showering with whale oil soap, or other solutions, from the syringe or hydroputt, will dislodge many. Others must be removed by hand; for mildew, dust with flowers of sulphur, freely.

Strawberries—Remove all grass and weeds, and mulch the ground with tan bark or short straw, before picking commences. Keep the beds well watered while fruit is forming, if there be dry weather.

Flower Garden and Lawn.

The earliest harvests of the year are gathered in the flower garden. The blossoming is to us fruition—and in June Nature's lap is full of flowers. Seed time still continues, many annuals may be sown. It is well to sow a little deeper than in May, and sometimes to lay a light board over the spot for a day or two, so as to keep the soil moist, but to remove it before the seeds begin to start much. Seeds of biennials may be sown at any time during this month or next, though with many kinds a tolerably long season, and vigorous growth the first season are essential to perfection of flowering the next.

There may be much taste exercised in the location of annuals and bedding plants, so that as they come successively into bloom, the garden may not appear bright and bare in spots, nor get mixed up blue and white and red and yellow, like the old fashioned style of "splashing" book edges—but so that there shall be a profusion of flowers growing in masses all over it. A mass of bloom need not be large, but only enough to destroy the awkward, lonely effect of single flowers or spikes of the same kind, looking up here and there all over a garden, but each by itself. This remark is not applicable to the more independent and robust flowers like foxgloves, balsams or Dahlias, which often are very effective quite alone.

Bulbs—Spring blooming bulbs when they have passed the flowering, should stand a while in the ground; then be lifted, with so much earth only as adheres to the roots, and laid with their labels in empty flower pots under some cover where they will dry in the shade, and will not be wet by rains. When dry remove the tops, wrap in papers and keep dry until planting time in the Autumn.

Climbers of all kinds should be kept within bounds, and under good training. Their appearance is greatly improved by very little time occasionally given to them.

Dahlias should not be allowed to blossom too early; a little early pinching in gives a much finer and better flowers late in the season when the weather is better adapted to them, and flowers are more double and last longer.

Evergreens—June is emphatically the month to transplant evergreens with best success. See article on p. 179.

Grass Edgings and Borders—Keep closely cut and trimmed always. If it burns in spots or looks ragged, water with liquid manure, and sift on a quarter of an inch in depth of fine loam.

Gravel Walks—First, plenty of gravel often raked; second, a good roller, often used; third, a shuffle hoe, to cut up weeds wherever they appear, are what will secure good walks. The weeds are left to dry and disappear on the surface, when not neglected, and grown too large.

Geraniums and Pelargoniums struck from cuttings in the open ground and which you intend to preserve, should be pinched-in freely, when they begin to grow rapidly, so that they may form compact, handsome, apple-tree-like tops, old plants require similar care or they will grow out of shape.

Hedges—Clip full grown hedges as often as they make growth enough. Evergreen hedges are best trimmed before they make their new growth. Young hedges must be pruned severely to force low branching. It is very easy to get top branches, but impossible to thicken up a neglected hedge near the ground, and such a hedge is neither ornamental nor useful.

Insects—Rose slugs, destroy with whale oil soap. The solution should be very dilute, and applied with a garden syringe and not a sprinkling water pot; they are on the underside of the leaves. This is also a defense against other insects. See *Insects* elsewhere in the Calendar.

Lawn—The grass of the lawn should be mowed just as often as a sharp scythe will cut *anything*. If you have water supplied in pipes from a head, by all means have a hydrant situated so that with a hose the grass may be often sprinkled. If moss comes in, after scarifying with a rake, a sifting of soil ¾ inch deep over the spot and a sprinkling of wood ashes, with a little salt, on the surface will probably destroy it.

Pinks and Carnations—As soon as they have done blooming, cut the main stalks back, and layer the side shoots. Cut back, whether you layer or not, for the flowers will be finer for it. Give seedlings plenty of room.

Potted plants require constant care and frequent watering; if the pots be sunk they require less, but must have water in dry weather.

Roses! Roses—Is there a family in this wide land with a rod of land attached to their dwelling, that has not a rose bush? Roses grow wild in almost every country, and by cultivation the number of varieties is rendered almost infinite. So numerous are they that the Horticulturist shrinks from enumerating even a few of the best sorts. The country gardens blush with them, and city corners and market places are redolent with their perfume. Severe cutting back after the bloom has nearly past, will secure on many varieties, particularly such as ordinarily bloom twice in the season, a full bloom again much sooner and better than otherwise. If roses depended upon for fall bloom are cut back to the sacrifice of their flowers at this season, they will blossom much earlier and finer for it. Keep climbers from whipping about in the wind, by binding them to the pillars or trellises. Prune all roses as soon as they have done flowering, letting no seed remain except on those varieties of cluster roses like the Sweet briar on which the clusters of coral-colored hips are so ornamental.

Seed Stalks—As soon as the flowers are past, remove the stalk, unless seed is wanted, in which case tie it up, or mark it in some way so that it shall not be disturbed. A heedless person in the garden may destroy some very choice seed if it be not protected in some such way.

Transplanting—As a general rule, transplant in wet days. If the plant can be moved with some earth, water the soil after it is set out, but if the roots are bare, add water at the time of setting out so as to cause the soil to settle about the roots. Protect well from the sun.

Verbenas need to be watched and pinned down so as to cover the whole bed allotted to them as speedily as possible. Ladies' hair-pins are excellent for this purpose. If the flower heads are all pinched off before they blossom it will greatly expedite this, and as soon as the bed is covered, it will burst into a sheet of bloom.

Green and Hot-Houses.

Most of the occupants of these houses do best in the open grounds. Some of the tropical plants, and others which it is desirable to multiply as fast as possible, are still retained under glass. Cuttings strike more readily inside, where moisture and shade are regulated at will. The remaining plants require an abundance of air, and should be watered frequently. It is now time to make provision for a stock of Winter blooming plants. Unless cuttings are put in soon, the plants will not have sufficient age and vigor to flower freely. A good supply of materials for potting soil should also be collected. Such compost or mixture is better after laying several months.

Camellias do well in the open border in partial shade. If retained on the shelves in the house, water and syringe often. Watch for and check the approach of insects. Cut back to a bushy well formed head.

Composts and Potting Soil—Composts make faster and better in the heat of summer than at any other time. Prepare rich compost of wood mold and fine manure, with a little garden soil, with any other desirable enrichment and work it over frequently. Before use it must be largely diluted with additions of pure peaty soil or wood mold, with lime and sand, and a shovelful of ashes and gypsum to the bushel. Have a good supply of properly prepared potting soil at all times in readiness.

Cuttings of Chrysanthemums, Myrtles, Hydrangeas, Fuchsias, Geraniums, etc., intended for blooming next season, may be made and potted.

Geraniums are in full flower, and should be watered freely. Insert cuttings and make layers to increase the stock of desirable kinds.

Potting—Many of the rapidly growing plants will now require more room, and must be transferred to larger pots.

Seedlings of sufficient size should be transplanted either to small pots or set in the open borders.

Water—Give as may be wanted. A little may be necessary night and morning upon plants in small pots in a dry atmosphere, too much endangers damping off.

Grapery and Orchard-House.

In cold graperies, thin the clusters of superfluous berries, and support the shoulders if necessary by tying to the cane or wires above. Cut off the bearing branches two or three leaves beyond the cluster and stop the laterals when they start successively, leaving one leaf only. Maintain abundant moisture up to the time that the fruit begins to color. Grapes in early houses will be ripening: watch against mildew on all—and dust with sulphur. Withhold sprinkling overhead when the clusters begin to color, and maintain a drier atmosphere. Whitewash, or otherwise shade the glass if there is danger of sun scorching, and give free ventilation.

Peaches and other house fruit, after a judicious thinning out last month, will simply require Summer pruning or pinching-in, to prevent too great a growth of foliage and to mature the next season's bearing wood.

Apiary in June.

Prepared by M. Quinby—by request.

More swarms will issue in this month, than in all the others of the season. A few stocks will send out a swarm before being crowded, or even full of bees. Others will be full, and a large part of the colony crowded outside for weeks before issuing, and sometimes remain in this way throughout the season. When an increase of colonies to the fullest extent allowable, is desired, there is hardly a season so poor for honey, that such stock may not be made to furnish one swarm at least, but they must be attended to in season, and a swarm *forced* out. An artificial swarm when established early, will do equally well with those issuing naturally. With the movable comb-hive an artificial swarm is made as readily as any way, by the process given last month for preparing colonies for Italian queens. All there is about it, is to divide, and examine afterward to see that each has a queen. It would be well to rear a few queens in the way given, (if you do not have the Italians) and introduce them, without making it necessary for the colony to rear one. The gain in the time of breeding will pay for trouble, beside the satisfaction of understanding a little of very curious natural history. It has been ascertained that a queen bee will lay from one to three thousand eggs in twenty four hours. It follows, that in the two first days of the lowest rate, she would deposit 14,000 eggs, which a good colony would mature—enough for a large swarm. But this is not safe to divide the second time, unless the season for honey proves to be extraordinarily good. Artificial swarms are not so readily made with the box hive, because the bees fly from the hive with a stick or hammer,a few times lightly : leave them quite five minutes, when the beating may be continued up to twenty minutes if necessary to get two-thirds out. You can now raise and look under the hive without any danger of stings. If the queen is with the new colony, they will be quiet after fifteen or twenty minutes; if not, they run uneasily about. When there is not room to set the box on each side of the stand as directed in May, the old one may be set in front of the other, moving either a little to equalize the bees as required.

Between two and three weeks after the first swarm, a stock is more liable to become queenless than at any other season; and after such swarms as are accompanied by young queens—in from one to five days. The loss may generally be known the next morning, and sometimes at evening, by their uneasy movements. It is important in such case, to give them a mature queen, or at least a cell containing a queen. They would probably rear one if brood was given them, but it would take about six weeks to get a queen and her brood ready to hatch; by this time the colony would be very much reduced.

The surplus boxes should now receive attention. As fast as the hives become full of bees, the boxes should be added. The new swarms may have them immediately, when very large, or when two good swarms have united. Take out a few with empty ones in the first as filled, fasten in the top of each box before using, strips of straight, even white comb, to secure regularity.

To keep the Italians pure, two methods have been recommended. One is to isolate as far as possible from all others. It is found that they will mix at a distance of two or three miles. It is necessary to have a colony or more that will furnish drones, to stand near the young queens to be impregnated. These, with native drones are in the way at home, must be removed to a distant yards. The stock that is reared for queens from, may be at home—unless it should be the only one to furnish drones—as well as the boxes for rearing the queens, until the cheens hatch, when they should be taken to the yards where the Italian drones are. Let them stand about eight days, or until the queen begins to lay. She may now be introduced, and the box and bees may be used to rear another queen. Although a dark colored queen *may* raise light colored bees, it is not apt to do otherwise, and I suggest that such be not used for breeding.

Another method of changing an apiary to the Italians, where there are a large number of bees, may be on the whole less trouble. Thus: take no pains to isolate, but rear the queens (from pure Italian brood) at home, and let them mix with the native drones. These will produce *pure drones*, but mixed workers. Introduce such a queen into all the stocks, the next season, perhaps before : if done soon, *all* the drones will be Italians. Now raise another set of queens from the pure one, and they will unite all the stocks, the next season, perhaps before : if done soon, *all* the drones will be Italians. Now raise another set of queens from the pure one, and they will quite certainly meet the Italian drones, and after all their produce will be pure. One queen will furnish eggs enough to rear five hundred or a thousand queens in one season. *Errata.*—In Apiary for May instead of "set over cover *two* boxes," read "set over cover *to* boxes."

Containing a great variety of Items, including many good Hints and Suggestions which we give in small type and condensed form for want of space elsewhere.

Crowded Over.—50 "Basket Items," in type.

Notes to Crop Reporters.—(1.) We are sorry to learn that, *by the delay of the mails*, the BLANK forms did not reach several persons in due time. They should have arrived on or soon after May 1st. This perhaps explains why many made no return in season for the present paper. If any one whose name is sent in has failed to get a copy of the blank forms, please let us know promptly. We have stereotype plates to print all required. Extra copies can be supplied to Farmers' Clubs, or others needing them.—(2.) Please make up the reports as near to the 10th day of each month as possible, and mail so as to have them reach this office on *or before the 15th, without fail.*—(3.) Only the crops largely cultivated in any county need reporting in columns **W** and **X.** The main object is, to get at the amount and prospects of the leading crops which are to affect the market prices.—(4.) Further inquiry and investigation may lead to a different estimate for columns **B, C, E, F, H, I, etc.;** please fill them up anew *each* month.—(5.) The State, County and name, should always be filled in at the head of the blanks. The omission of this in three reports, compelled us to leave them out.—(6.) We have assigned a *Register Number* to each name, as will be seen in the tables page 186. It will greatly assist us in compiling and comparing the tables, if each reporter whose number is given, will mark his own register number plainly on the left of *each* monthly report.——(7.) Letter Postage is required for the blanks written on. Though this is a public enterprise, from which we can derive no special pecuniary benefit, while it involves hundreds of dollars, in expense and time, in preparing blanks, collecting the returns, etc., we shall quite cheerfully bear all the cost, and those sending the reports may prepay postage to 15 cents from their next subscription account. We would inclose the stamps in a letter but this would require extra labor, and additional outlay for postage. We trust those who take the trouble to collect and forward the reports will find abundant satisfaction in their labors, by the usefulness to the country at large as well as to themselves, of these reliable statistics. If such information were collected by the Government, as it ought to be, an appropriation of twenty or thirty thousand dollars would doubtless be required to gather no more useful reports than those we shall give.

The Strawberry Show.—In anticipation of a fine show of this delicious fruit, which so charmingly hand in hand with the rose, introduces the season of fruits and flowers, we again invite all who are interested in Strawberries, and their culture, to visit the office of the *Agriculturist* on the 20th and 21st of this month(June). Persons intending to exhibit are referred to the announcement of the show on page 192, in which a slight change has been made. We should have a few days notice of the number of samples we may expect from the principal exhibitors, in order to provide for all, and hope this suggestion may be complied with. The results of this exhibition will, we hope, prove by careful weighing and measuring single berries and quarts, that a decided advance in strawberry culture has been made, and that in this, America may offer a challenge to the world.

Strawberry Premiums are again offered for August, at which season, plants of new growth will be vigorous, and ready for transportation by mail or otherwise. See particulars on page 192.

Fruit of Sorghum Seed.—We are getting returns in various ways from our distribution of this seed five or six years ago, and now by mail receive a sample of excellent and beautiful, light colored sugar from C. Cory, of Lima, Ind., whose interest in the culture of the sorghum is widely known. Mr. Cory received the 2d and 3d premiums at the Sorghum Convention in Adrian, Mich., in April, and is the inventor of one of the approved evaporators now claimants for public favor. His interest in this subject dates from the reception of the seed distributed from the *Agriculturist* office.

South-down Sheep.—Mr. Taylor, of Holmdel, N. J., has exhibited no little enterprise in his efforts to introduce improved sheep into our country, and we hope his Show and Sale, advertised in this paper, will attract the genera. attention it deserves.

Humbugs.—The reader should set it down as a general rule that those unknown dealers who offer the most certain cures, and the largest amount of gold, silver, precious stones, books, pictures, engravings, and what not, for the least money, and who tell the most plausible story, are in nine cases out of ten those who give the least return for money invested with them, if, indeed, they make any return at all. Poor, worthless copies of engravings with high-sounding names, can be got up at trifling cost. Any one having a business that will pay a high salary "and found," can hire plenty of persons at his very doors to take the situations offered. A very large number of persons who have written to us, and who may hereafter make inquiries after this and that splendid money-making scheme advertised, will please consider the above as an individual answer. When they inquire about a good thing, we will try to respond; but in this matter, silence must *not* be construed into approval.

The Bureau of Agriculture referred to last month, has received the sanction of both Houses of Congress, and the President. The new Department is to be under the almost absolute control of a "Commissioner of Agriculture," nominated by the President and confirmed by the Senate. With a right kind of a man at its head, great good might result. We fear, however, that our worthy President is too much engrossed with other cares to give the subject due consideration, and that, as usual in such cases, he may nominate for the office a man without suitable qualifications. The fact that Watts was a good gardener at the White-House, did not prove him fit to be a "Brigadier General;" nor will the fact that any man is a good florist, or a successful wheat grower, or an excellent dairyman, be a guarantee that he can look after and foster the general and varied agricultural interests of our country. We repeat, emphatically, what we stated last month, viz., that only an energetic man, of the highest order of intellectual and administrative ability, should be appointed to the station of Commissioner of Agriculture, in this, the greatest agricultural country of the world.

Large Farms for $10 Each.—Newspaper advertisements and circulars, without number, have for years past announced "homesteads" and "farms" for from $1 to $5 per acre, and "lots" for a little more for a plot 20x100 *feet* in some village to be about to be, or a little larger area in some man-avoided place, away out West. This humbugry is all done away with now. Uncle Sam has stepped in and generously offers **80 to 160** acres of land to every head of a family —male or female—who is a loyal citizen, native or foreign born. The only conditions are, that the recipient pay in $10 to meet the expenses of the survey, etc., and go upon and occupy the land for a period of at least five years—in other words, make it his or her *homestead.* Minors, who have served at least fourteen days as volunteer soldiers,can choose a farm of any unoccupied lands belonging to the Government. Of land sold at $1.25 per acre, 160 acres are open for free entry ; of those now valued at $2.50 per acre, only 80 acres can be chosen. We will publish the Law in full, in the July *Agriculturist*: it was signed by the President at too late an hour for us to crowd it into this number, already over-full.

The Dog Show at Barnum's.—There has just closed at the American Museum in New-York, a very interesting exhibition of dogs. The chance of Show-ists," offered very liberal prizes—from $1000 for the largest and handsomest dog, down to 2d and 3d premiums for the best dogs of various pure breeds, both useful and ornamental. An immense Siberian bloodhound took the $1000, but to enumerate the others which for great beauty, and grace, or for faithfulness, sagacity, power, or ferocity even, gained the admiration of thousands of visitors daily, is beyond our power, for lack of space. Exhibitors may not in all cases have coincided with the Committees who made the awards, but the public was gratified, and Mr. Barnum's reputation has not suffered.

Apropos.—Mr. B., has announced a Baby show which promises to amuse the public as much as did the form er one. An 8 months old, 1½ lbs. baby, will be there.

Noticing Advertisements.—Twenty or thirty of our advertising patrons have requested editorial reference to their business notices, and we would cheerfully do so in some cases ; but that would be unjust to others, and we must treat all alike, by advising our readers to look at all—for as a whole they embody a vast deal of information, important to almost every body.

Vest-Pocket Lexicon, by Jabez Jenkins, is a condensed Dictionary, 2½ by 3 inches, ½ inch thick, containing about 20,000 words, mainly those not familiar to everybody, including scientific and technical terms. The explanations of the words are rather too brief to be fully satisfactory, but on the whole, the book is a convenient *wade-mecum*, easily carried in the vest-pocket. Price, according to style of binding, 53 to 75 cents. sent by mail.

Summer Vines for Verandas and Arbors.—Of those which it is not too late now (June 1st) to plant, and which can be got in small pots at the Florists, we name the following: *Ipomea Learii*—This is a dark, rich blue convolvulus, with flowers larger than the common Morning Glory, growing 15 or 20 feet high. *Cobea Scandens*—Very rapid grower, 15 to 50 feet high, and has large, purplish, bell-shaped blossoms. *Lophospermums*—Two sorts, pink and pale purple, same hight as preceding. *Maurandias*—Three kinds, pink, purple, and white, 10 feet high, very desirable. Great bloomers.

Flowers.—(D. T. of Clinton, N. Y.) The extra fine specimens of Balsams and Asters which you saw at the Fair, were produced in this way: The plants were set 18 inches apart, the side shoots were kept pinched in, and the whole vigor of the plant thrown into a few blooms at the top. The balsam seed used was *several years old*.

Barren Flower Beds.—"Elsie." Yours is not an uncommon case. Your plants having stood so many years in the same ground, have become overgrown, and have nearly exhausted the fertility of the land. The ground is damp, heavy, pasty, and nothing seems to grow naturally in it. Now, give the beds a thorough overhauling. Dig out a part of the old soil and bring in new from the kitchen garden. Then work in a little old manure, and leaf-mold and sand. In setting out the plants afresh, divide the roots and set out only the youngest part of the root. If there are any over-hanging trees, not valuable, down with them; their shade and the action of their roots will spoil any garden.

New Drummond's Phlox.—"Sophy." One of the newest and best is the *Radowitzii*, the flowers being rose colored with white stripes running from center to margin of each petal. It blooms early and profusely, like the old sorts.

Origin of the Delaware Grape.—"W. D." of Morristown, N. J., thinks this a useless inquiry. We beg leave to differ. It is of interest as a matter of intelligence to know the origin of all fine fruits, of all good breeds of cattle, of all useful inventions. The origin of many of our finest fruits was without human intervention. But others have been secured by the skill of man, through planting seeds, and hybridizing. If we knew more of the circumstances attending the origin of chance fruits, it would help us very much in our efforts to originate new varieties.

Mice Gnawed Grape Vines.—(Edw'd Smith.) Laying down grape vines in the Fall was very well, but covering them with straw was not wise, at least for your locality. Next Fall, simply lay upon the canes a few bits of board, or even poles to keep them down close to the ground: of all *coverings* earth is best.

Strawberries—Comparative merits of the staminate and pistillate varieties. "Mrs. E. A. L." The information you desire has been given in past numbers. See basket for May. Any of the varieties indicated there are good enough for field culture. The Wilson's Albany, a staminate, bears more abundantly than any pistillate we have ever tried, but with us the plants are not so enduring as some others; and the fruit, though large and fine, is too acid for our liking. We prefer a little less of the fruit of the Triomphe de Gand, while the plants of this latter do well with us.

Unfruitful Gooseberries.—S. T. Wheeler, Kosciusko Co., Ind. Prune freely in the Fall, cutting out old wood and shortening in the new. An old bush may be cut back one half to advantage. If still inclined to wood without fruiting, pinch in the summer growth.

Training Blackberries and Gooseberries.—"W. K." Beaufort, S. C. The New-Rochelle blackberry should be set in rows about eight feet apart, and four feet in the row. It may be trained to wires on posts or tied to stakes. It should be shortened in at the top and about a third taken from the side branches. Gooseberries should be thinned.

Grafting the Hickory Nut.—W. Minton, Morris Co., N. J. The shagbark can easily be grafted upon the common pig nut, early in Spring, and it is stated also, and we know no reason to discredit it, that whip grafting succeeds with green shoots while growing vigorously, say in July or August, shading the grafts.

Gas tar on Apple Trees.—D. P. Judson, of Fairfield Co., Conn., having 50 very thrifty 4-year-old apple trees, painted them with a coat of coal tar to prevent girdling by mice, as recommended in an agricultural paper. In the course of the Summer suckers were thrown up most abundantly and a swelling of the bark above the tar was noticed as if a powerful stricture had been applied. The tar was at once removed, but its effects were long visible. In the case of one tree the bark drew off nearly all around.

Crown Grafting.—J. D. Douglas, of New London Co., Conn., says he much prefers crown grafting—that is, inserting the cions between the bark and wood—to any other method. He has practiced it for 15 years with entire success, using only a fine saw, sharp knife, and a steel probe to part the bark from the wood. He thinks cions are more likely to grow, and the wounds to heal sooner. Mr. D. uses cement made of 4 lbs. rosin, 1 lb. beeswax, and ½ pint linseed oil, melted together.

Honey Locust Seed.—C. E. Wood. This seed is covered with a thick tough skin and sprouts sooner for scalding, but grows without. Most seeds of evergreens sprout readily, but need a screen or shade for the first season after they come up. Nurserymen plant them in open cold frames and shelter them with a lattice frame made of laths, which diminishes the sunlight.

Weeping Willows.—"J. G. I." Try a "cutting," as large as your arm or no larger than a goose quill—10 feet long or 10 inches; set it in any soil but a blowing sand, a moist loam is best, and it will strike at almost any season of the year when the frost is out of the ground, though early Spring is the best time.

Grasses for Minnesota.—"J. G." of Rosemount, wishes to know the best kinds for that State. Probably the varieties that flourish at the North generally would do equally well there. Herdsgrass or Timothy is one of the best for hay, but does not last long in pasture. White and red clover, red top and furze, fowl meadow, and Kentucky blue grass make good pasture. A variety is better than any one kind. The only cultivation grass needs is the sowing of seed, when the land is laid down with spring grain. Top dressings are of service when the yield begins to diminish; no kind of manure comes amiss.

Alfalfa.—"L. B." of New Russia, N. Y. Lucerne is called by this name in Buenos Ayres. In some respects it is better than red clover. It sends its roots deeper into the subsoil and for this reason withstands drouth better. It grows very quick after it is cut, yielding several crops in a season, in soil adapted to it. It does not succeed well in thin soils, or in those of a compact subsoil. It is not much raised at the north and experiments are needed to show if it will flourish. We advise no one in the latitude of our correspondent to attempt it, except as an experiment.

Prairie Grass for Hay.—"A. D. C." of Ind., wishes to know if this hay is merchantable. Any thing that has value will sell. Whether it will pay to send this hay to market, depends upon his location. In some places it will not pay to market corn. If the hay makes good fodder where it is grown, it will be good fodder, and command some price in any market.

A Package of Oats—The White Poland.—Mr. J. V. M. Wyckoff, of Somerset Co., N. J., informs us that four years ago he received through the Seed Distribution of the *American Agriculturist*, one of the ounce parcels of White Poland Oats. These he sowed in drills in a blackberry garden. The hens destroyed about half of the yield; the rest was sown in a field the next season and yielded 24 quarts. These yielded 20 bushels the next year, which were scattered through the neighborhood and yielded largely. The present great (very bushel that could be obtained was in great demand for seed, at a much higher price per bushel than any other kind. Thirty pounds are reckoned as a bushel, but they weigh fully 80 lbs. to the sack of 2½ bushels. They continue to yield well and weigh heavy, and Mr. Wyckoff says they are esteemed a very great improvement. So much for the history of a single free parcel of seeds—a similar history belongs to tens of thousands of parcels of different kinds of seeds sent free from the *Agriculturist* office, to every part of the land, during a few years past.

Large Yield of Wheat.—J. W. Joseph, Portage Co., Wis., writes that he sowed 1¾ quarts of Golden Trape wheat, on a piece of land 10 rods long and 11 feet wide, from which he harvested 2 bushels and 12 quarts of fine wheat. A very large yield, being 'at the rate' of 57 bushels per acre.—What is its quality, and season?

Cabbages—Corn for Soiling.—"S. W. R." Perrymansville, Md., writes us, that, in his experience, cabbages produce more feed than Rutabagas, sugar beets or carrots, with less trouble to raise, less to prepare for the cattle, and making quite as much and as good milk. On this matter we are willing he should speak for himself. He also writes, that corn, sown broadcast and cut green, produces more soiling feed to the acre, than oats, barley, wheat or southern peas (which lids cattle will not eat) and whatever is left in the field is excellent for winter feed, if cut and cured seasonably, all which is true. The value of the corn plant can not be overstated.

Beans in a Rotation.—They come in properly before wheat. They of course make some draft upon the soil, but not so great as a grain crop.

Sugar Beet Culture in Ohio.—Prof. F. A. Mott, of Columbus, O., succeeded in manufacturing a fair sugar from the beet, and estimates that 16 tons of beets can be raised upon an acre, capable of producing 6,000 lbs. of sugar, and 600 gallons of syrup. Calling the syrup worth 40c. per gallon, and the sugar 6c. per lb., the product is $600 per acre. Prof. Mott plants 10 acres this spring, with seed imported from France. The above we gather from the report of Secretary Kippart of the Ohio State Board of Agriculture.

Syrup from Sugar Beets.—"P. H." of Brighton, Michigan, wishes to know the process of making syrup from beets. There is no simple and cheap process adapted to the farm; a large factory is required for working profitably. It is much better to get syrup from the sorghum which is easily raised on new lands.

Large Increase of Potatoes.—W. Beckwith, Johnson Co., Kansas, says he cut one bushel of Black Mercer potatoes into pieces of two eyes each, planted them on ¾ acre of poor soil, and harvested 90 bushels large potatoes. [Rather thin seeding—only 1½ bushels of potatoes to the acre?—Ed.]

Mixing Potatoes.—We can get new varieties of potatoes only from the seed. The tubers of different varieties will not change, even if planted together

Draining keeps the Land Moist.—"S. K." of Dayton, O., wishes to know how this is effected. The soil is made more porous by drains. The air from the surface follows the water as it sinks into the drains, and diffuses itself through the soil, parting with its moisture as it comes in contact with the cooler particles of soil. As the air is constantly changing, the soil is always receiving moisture in the dryest time.

Canada Thistles.—This plant is propogated partly by seed, and partly by the spreading roots. The perpendicular root is not the true root: *that* is a horizontal stem shooting out, right and left, from the base of the perpendicular stem, a foot or more below the surface. But if this upright stem be perseveringly cut off at the top of the ground, the whole root will gradually die out. The wonder is often expressed, that the uncounted millions of seeds grown each year do not spread this pest faster than they do. They would do so, if a multitude of the seeds were not aborted, and still others were not destroyed by a grub which eats into the flower at its base. A merciful Providence, surely.

Seeds in the Manure Heap will be destroyed if the fermentation is complete in all parts of the heap, and continues long enough. But this seldom happens. If the weeds are dry, it is a much safer process to burn them. If green they will help the fermentation of the heap and perish.

The Italian Bee.—Urgent calls are made for information upon this insect, by "T. B. W." and many others. All who have them to sell, mixed, or pure, of course, affirm their great superiority. But Jonathan remembers that this is an age of humbugs, and waits other testimony. He shall have it in due time. Those who are best prepared to give an opinion would not like to publish it yet. It is thought by some of these gentlemen that this bee will make twenty five per cent more honey than the common variety. The Italian bee has not yet been long enough upon trial in this country to ascertain this fact, if it be one. As the pomologists would say, it is on the list promising well. We will hope for good things from it. So far the main effort has been to multiply queens.

Peach Tree Borer.—"T. B. R." Henry Co., Ind., says: "I have tried planting tansy around my trees, for two years past, and not a single tree has been attacked by the borer, while those without tansy have almost all been more or less injured. I have seen it tried four years on other trees with entire success. The tansy is planted very close to the tree, and so as to surround it. It need not be allowed to spread but a few inches from the tree."—Strong scented herbs are offensive to most in-

sects. Fruit growers have much to learn and to gain in studying their instincts, but it is said that after a while they get used to tansy, and worse things.

Centipedes.—The worms sent us from Baldwinsville, by "L. S. P." are centipedes. He states that they are very abundant in the gardens in that region, destroying strawberry plants, pink roots, tomatoes and even potatoes and apples. One of the best remedies for insects is an application of coarse salt at the rate of about six bushels to the acre. We have also had occasion to notice that insects disappear from the ground that is highly manured and deeply worked. We suggest trenching, spade and manure.

The Cut Worm in Corn Ground.—"J. T. R.," of New-Guilford, Pa., recommends cider bushes one or two feet long, scattered over the field, a rod and a half apart when the corn comes up. The worms seek shelter under the bushes, and are attacked by ants and killed. He has seen half a pint of worms under a single bush. The remedy is easily tried.

Bottle the Insects.—Dr. W. S. Kimball, of Monmouth Co., N. J., informs us that many farmers in his vicinity, have adopted the plan frequently recommended in the *Agriculturist*, of suspending a large number of open bottles of sweetened water in their fruit trees, by which means they entrap an abundance of insects of various kinds. They find their fruit much fairer and freer from worms since trying this method. The bottles have to be emptied and refilled occasionally.

Destroy the Millers.—A New-Jersey farmer writes that he has very much improved the appearance and healthfulness of his fruit trees, besides saving good crops of fruit, by making a blaze among the trees in the evening. He noticed that the millers were plenty early in the Summer, and again towards Autumn, and he only kept the torches burning at those periods, say one week at each season. When first lighted, hundreds of millers were attracted to the flame and destroyed during a single evening, and as each miller is the parent of hundreds, it is easy to see the advantages of such wholesale slaughter.

Pear Slugs Destroyed by dusting with fine dry Earth.—H. E. Davis, Allegany Co., Pa., says his young pear and quince trees were badly infested with the slug which made sad havoc with the leaves. He entirely destroyed them by dusting with dry earth, which, adhering to the slimy skin of the insect, caused death. The rose slug can be destroyed in the same way, repeating the dusting frequently. Dry lime or wood ashes is better than sand or dirt.

Peach Borer.—("Novice.") This is one of the greatest enemies of the peach. It assaults the tree just at the surface of the ground, and will kill it, if not exterminated. Attack it without mercy. Take an old table fork, with one prong broken off, and, having drawn away the dirt from around the roots, ferret out the worm from his hiding-place. The exuding gum and the chip dust will show where he is. Dig him out and kill him. Then scrape the collar of the tree clean, and pour on a quart or more of scalding water.

Fleas.—A subscriber, we should not like to tell where he lives, complains of these annoying insects, introduced by pigs sleeping under the barn. The pigs should have been in a sty, with plenty of muck and mud to roll in, when they would have killed the fleas and made heaps of manure. Fleas are the scourge of the slack, slovenly farmers; it is perhaps well that they have something to keep them lively—even fleas. Clean out under the barn, the sheds, the sty, have a place for your dogs (a grave we should say), a place for your hogs, and the nuisance will be speedily abated. Elbow grease at the end of a shovel is much better than lime.

Hen Lice.—"C. C." recommends white-washing the house, and using sassafras roosting poles as a preventive. So do we. The sassafras has a very strong odor

To kill Rose Bugs.—(Mrs. James.)—Some persons succeed by scattering ashes or air-slaked lime on the leaves when wet with dew. But it is hard in this way to reach the vermin on the underside of the leaf. A surer method is to use a garden-syringe with upturned rose, and dose the slugs with whale-oil soap, at the rate of 1 lb. of soap to 8 gallons of water. Four lbs. will make a barrel full. Apply morning or evening. Two or three applications will generally suffice.

To Prevent Hog's Rooting.—A Canadian subscriber wants to know how deep to cut a hog's snout to prevent his rooting. We should say, the *tendon* that lifts the snout must be severed, to make a permanent cure. A wire in the snout, worn as a jewel, is generally a perfect safeguard against this evil. It is less troublesome, and less barbarous. Piggy submits with good grace, not knowing but the jewel is an honor.

Dog Cured of Sucking Eggs.—One way is to cut his tail off close behind his ears; another is told by a correspondent in Cecil Co., Md., and as many a dozen eggs is disposed of by the favorite terrier who hunts eggs as well as rats in the barn, the hint may be valuable. "As I valued the dog highly for many good qualities, and did not like having it killed, I made many inquiries, and neighbors informed me if I would boil an egg and place it hot in the dog's mouth and hold his jaws together until it burned him severely, he would not trouble the hen's nests any more. I tried it—and he has not touched an egg since."

An Egg within an Egg.—This is rather rare, but not unheard of among "fast hens". It indicates good breeding and rather high living. Your egg is a whopper, about seven by ten.

Sick Hens.—"J. R. K." Phenix, R. I., writes of his fowls, that they have a noisy breathing, terminating in a rattling in the throat. The head about the eyes swells. There are discharges from the nostrils at first thin, and in five or six days thick. They sneeze and make a quirring noise.—The disease is the Roup. Roup is caused by the presence of numerous thread worms in the wind-pipe, which are said to be generated in the blood, principally at times when a want of iron is noticed in that fluid. Remedy.—Soak barley in spirits of turpentine, giving a few grains every morning with some pills composed of 1 drachm of sulphate of iron, and 2 tablespoonfuls of flour. Preventive.—Give the hens a clean house and freedom, with green food and meat or insects.

Long Toes in Sheep.—One of the causes is confinement in the yard or sheds during the Winter. They usually wear them off in the pasture during Summer, especially in gravelly rough land.

Hoven in Cattle.—This is occasioned by eating excessively of green succulent food, usually after being kept on hay and dry food. "The gas generated in the stomach swells the animal, and sometimes causes death. The knife should never be resorted to. If a stout rope of straw, as thick as your wrist, be made, and forced into the mouth, and the ends tied behind the horns, it will afford relief. The animal being turned loose in attempting to get rid of the straw raises the neck and head in such a position as to let the gas out. The passing down of a tube by one who understands the anatomy of the throat will also relieve the animal. But the straw seldom fails, and any one can apply it." (So says a subscriber.)

Horse Refusing Hay.—"A Young Farmer," says of his horse ten years old, that he is unable to swallow hay after he has chewed it, while he eats other provender well. He keeps thin though in good spirits.—The eschewing or throwing out of the food from the mouth after mastication, no doubt, arises from the state of the Molar or double teeth. Examine the mouth of the horse, and if the teeth are found sharp and jagged, they must be rasped smooth, with a proper tooth rasp.

How many Pounds of Milk to a Pound of Cheese.—"O. B. P." of Potsdam, N. Y. gives the following account of his experience to determine this question, beginning May 15th, ending Oct. 30th, 1861. All cheese made prior to Sept. 20th, was shipped Nov. 12th, the remainder Nov. 26th. The night's milk was set 3 to 5 inches deep in tub and pans. In the morning it was skimmed, the cream being made into butter (7 pounds to 100 pounds of cheese,) and the morning's milk added. Cheeses made in May required 11 pounds of milk for one pound cured cheese; those made in October 9¾ pounds, the average of the season being 10 pounds. Cheeses made in May required 9 pounds of milk to one pound of green cheese; those made in October 8¾ pounds, the average of the season being 9 pounds. September 30th, he made cheese in the proportion of 8¾ pounds of milk to one pound of cheese when 60 days old, and he estimates the shrinkage on 100 pounds of green cheese made in May at 17 pounds, and that made in October at 7½ pounds, to the 100 lbs. the average shrinkage being 11 lbs. in the 100.

To Expedite Crops.—In certain backward seasons and localities, the corn crop, root crops, and vegetables in the garden, need a little stimulus. For the corn crop, manure may be applied in the hill. Or if the corn is up, and looks yellow and stunted, use at the first hoeing a tablespoonful of guano, or superphosphate, or a handful of plaster and ashes, to a hill, distributing it evenly in the soil. But special reliance must be placed upon the cultivator and hoe. Both in garden and field, the weeds must not be allowed to gain any headway. In the garden, kitchen slops, or other liquid manure may be used, once or twice a week, according to their strength.

Hen Manure on Corn.—"J. R. T." of Otego, wishes to know the best way to use it. It contains a good deal of ammonia, and should not come in contact with wood ashes. It may be mixed with three times its bulk of plaster, and eight or ten times its bulk of muck, peat, or garden mold, and be used in the hill or for a top dressing after the corn is started, a handful to the hill. The compost should lie a few days under cover before it is used. It is very valuable for all field and garden crops.

Lime on "Pound" (Yard) Manure.—A subscriber to the *Agriculturist*, spread his manure last fall on land intended for corn, and then covered the entire field with slaked lime, and asks our view of the operation. The danger was great that through the influence of a mild rain or the natural moisture of the manure the lime would act upon it and disengage the ammonia which it does very readily, and this most valuable ingredient would be lost. A heavy fall of snow might have saved it—or prolonged rains—but we utterly condemn the practice. Lime and unleached ashes should never come in contact with ammoniacal manure.

How much Leached Ashes to the Acre.—"G. B. H." of Galt, C. West, asks this question. There is little danger of using *leached* ashes in excess. It is a manure that lasts longer than most others, showing its effects for a dozen years or more. Ten or fifteen two-horse loads to the acre will make a good dressing.

Rogers & Gest's Fertilizer Overestimated.—We have received the following comunication from Dr. Pugh, Pres. of the Pennsylvania Agricultural College:..... "Certain analyses of manures made in our College Laboratory were published in the May number of the *Agriculturist*, and the selling price and the correct calculated value of each given. One of them, styled "Rogers & Gest's Ammoniated Superphosphate." Though the specimen sent to me as such, proved to be, as the analysis showed, nearly pure Sulphate of Ammonia, the calculated value of which was $75.80 per ton, while the selling price of the manure it purported to be was $45.00. Several persons wrote to ascertain where they could get Rogers & Gest's manure. I candidly told them all against the danger that the specimen which we analyzed was not a correct specimen of that sold as Rogers & Gest's Ammoniated Superphosphate and assured them that they would only be safe in purchasing on a legal guarantee that the manure contained what we found in it, and wrote also to Messrs. Rogers & Gest asking if they could supply us mannre of the standard we had received at $45.00 per tun. They sent me a 10 lb. sample for examination which I found to be a very different article from that first examined as the following analysis shows:

Phosphoric acid soluble in water	4.49 p. ct.	at 12½c. p. lb.	$0.56
Phosphoric acid insoluble "	5.13 " "	4½c. "	.23
Sulphuric acid	21.35 " "	1c. "	.21
Nitrogen	1.43 " "	17c. "	.24
Potash	1.22 " "	4c. "	.04
Calculated value per hundred pounds			$ 1.28
" tun			25.60
Selling price per tun			45.00
Loss per tun to the farmer in its sale			19.00

I am sorry that an error committed somewhere (though not by us) has led to the association of so high a price with so poor a manure. In conclusion the farmer is reminded that the principle upon which these manures are calculated is not dependent upon any theory as to the agricultural value of the elements of manure. The price given to *each element* is simply that at which it can be purchased in the market. When we say that insoluble phosphoric acid, as in bones, is worth 4½ cents per pound, we mean that this is its market price when free from any admixture, as in combination I can only urge upon the farmers the necessity of refusing to purchase any bf the costly fertilizers without a *guarantee* as to what they contain; and finally if American dealers refuse their guaranty it would be better to import manures from England, from whence at least the superphosphates could be bought and sold on legal guarantee in New-York and Philadelphia at prices as low as those we have used in calculating the value of American manures." E. PUGH. *Agricultural College of Penn., May 3d, 1862.*

Home-made Hand Harrow for Root Crops.—A convenient, home-made implement for running between the rows of beets, carrots, turnips, etc., is formed by driving spikes through a plank of any desired width, to be drawn or pushed between the rows. Round up the forward end, attach a handle, and load with weights if needful. Run this implement between the rows weekly and there will be little left for the hand-hoe.

Agricultural Fun.—A waggish friend out West writes us that "the best way to make farmers grow

Madder, is to *poke* 'em with sharp sticks !"—A novel connection between *Phytolacca* and *Rubia*.

Currant Wine.—There is always a market for it in this city. The price depends upon quality. There are men who make a business of disposing of all such products of the farm and garden, who would sell it probably to better advantage than the producer.

Cotton in Caraccas.—Mr. J. E. Willet, an extensive planter of New Granada, assures us that he produced last season 2,500 pounds of cotton of excellent fiber upon two acres of land, at a cost not exceeding $25 for cultivation. The world will furnish cotton somewhere.

Making Wines.—Messrs. Clark, Selden, and others, Onondaga Co., N. Y., wish instruction about making wines. Strawberry, currant, gooseberry and raspberry wines and cordials are made after different recipes, scarcely any two people following the same. They vary from 1 quart pure juice to 3 quarts water; from 1 pound of sugar to the gallon, to 3 or even 4 pounds, and of course the wines vary from very mild wine-like beverages to sweet, strong cordials. A very satisfactory currant wine is made by using half water, half pure juice, with 2 pounds of white sugar to the gallon. After the juice is expressed from fully ripe well mashed fruit, let it come to the air as little as possible, add the water and sugar together, and put it in a *perfectly* cleansed barrel or other large close vessel, the larger the better, in a cool cellar, filling within an inch or two of the bunghole, over which lay a cloth, until the fermentation has nearly passed. Preserve in a keg or demijohn, similarly treated, enough to fill the barrel full, when the fermentation has nearly ceased, at which time (after 1 month) it may be bunged up, leaving only a small vent at the bung. It may be bottled in October, or stand a year or two on the lees.

Preserving Eggs.—C. N. Bement, in an article in the Genesee Farmer, says that eggs for preservation should be removed from the nest daily, and laid down as fresh as possible. A good way is to pack them, small end down, in stone jars, and pour on a strong lime water in which two handfuls of salt to four gallons of the lime-water are dissolved. Keep in a cool, dry situation.

Good Keeping Pumpkins.—We have now (May 15th,) on our Exhibition tables, a large pine apple pumpkin (60 lbs.) raised in Monmouth Co., N. J., last season and presented to us in Autumn by Mr. S. B. Conover, of Washington Market. The pumpkin is perfectly sound, and would apparently keep much longer, but we wish to plant the seeds, as they can not be found at seedstores. A pumpkin of this kind proved excellent when made into pies earlier in the season.

Destroying Moles and Gophers.—J. Kearns, of San Andreas, Cal., rids his grounds of these destructive pests, by sinking tin cans (lard cans 3 to 6 inches square, and 10 inches deep,) below their burrows. Once in they can not get out, and he has taken 6 to 8 at a single haul. It is advisable to put small pieces of turnips or other vegetables in the cans to attract the gophers, and after the can or earthen pot has been sunk even, the run should be cleaned out and a board or stone laid over the top, a little above the track to shut out light, covering the whole with earth. Mr. K. also poisons them by burying in their runs potatoes in which strychnine is inserted.

Squash Bugs, (writes "J. B. S.", Hilsboro' Co., N. H.,) will crawl on cool nights under pieces of board laid upon the ground among the vines, where they may be found and killed in the morning.

Scale on Apple Trees.—W. Gutteridge: Your trees are covered with 'bark lice' or 'scale', as the twig sent abundantly testifies. The trees will be greatly injured if not killed, unless the insects are destroyed. Make a strong soap suds, with 1 pint of soft soap to 2 quarts water; or 1 lb. potash to 1 gallon of water, and wash the affected parts thoroughly in May or June with a scrubbing brush and the liquid. Illustrations and full directions were given in Dec., 1857.

The "Stuyvesant Pear Tree."—This noted tree, 200 years old, standing at the corner of Third Avenue and Thirteenth Street, this City, we found putting forth its blossoms on the 6th of May, or 12 days later than last year.

Agricultural College of Pennsylvania—Change of Name.—This institution was at first chartered as the "Farmers' High School of Pennsylvania." The requisite legal steps having been taken, the Trustees at a meeting on May 6th, changed the name to that of the "Agricultural College of Pennsylvania," the latter name better representing its character and associating it more directly with similar institutions.

Flower Show of the Brooklyn Horticultural Society.—Lovers of flowers enjoy a great treat, once a year, at the Spring show of this flourishing Society. This year the exhibition was very well sustained in the departments of rare and beautiful exotics. Beautiful leaved plants were in profusion from the magnificent *Cyanophyllum*, 8 feet high, with leaves thirty inches long and 10 wide, to the beautiful *Sonerilla*, of which we gave a picture in the last *Agriculturist*. The show of Orchids was excellent; of *Daphne cneorum*, there were some noble plants; and Azaleas in great perfection, made the room glow with their many tints. There was a most instructive show of Ferns, which was particularly rich in those of variegated foliage. There was a Mocha coffee tree in fruit, and Palms in variety: Roses, Pelargoniums, and many very rare and more common green-house plants, with hanging baskets, moss baskets, Wardian cases, etc., made it one of the finest exhibitions we have ever had on this Continent.

Information Wanted About Bees.—"J. W. H." Hartford Co., Conn. Langstroth on the Honey-Bee, is clear and practical in its instructions, (price $1.25.) Quinby's Mysteries of Bee-Beeping, also a good, common sense book, (price $1.) Both should be perused by those studying the nature and habits of the bee, and either will be a safe guide.

Massachusetts Agriculture.—The Annual volume containing the report of the Secretary of the Board of Agriculture, with reports and valuable statistics, is received from the Secretary, Mr. Flint. It contains a very interesting account of the native Mammalia of the State, and their relations to agriculture, from Mr. E. A. Samuels, who has had charge of this department of the State collections, which, including all branches of Natural History, are now under the charge of the Board of Agriculture. The reports of Dr. Loring, chairman of the committee on Cattle breeding and Dairying; of Mr. R. S. Fay, on the protection of sheep and against dogs; and Mr. J. S. Grennell, chairman of the committee on the wastes of the farm, are very valuable contributions to agricultural literature. We can not express too highly our appreciation of the successful efforts of the Mass. Board of Agriculture, and of Mr. Flint, in particular, under whose auspices during the past year not only the volume before us, but the excellent edition of "Harris' Insects," and the "Manual of Agriculture" have been given to the public.

Country Houses.—We have frequent inquiries in regard to plans for building country houses. Our friends who purpose building will do well to consult Cottage Residences and Cottage Grounds, by Downing. (Price $2.) It is full of practical, good hints.

Wool Growing States—Sheep Book.—"What State is best adapted to wool growing?" "A Subscriber" of this City is the inquirer, and to him and others we must say we can not tell. Sheep will do well every where, in every State and Territory in this broad land from the Aroostook to the Sacramento; and from the Gulf to the great Lakes, on the plains of Texas, Kansas and Colorado, wool can be more cheaply produced than anywhere else. Distance from market, is the disadvantage which the producer has to contend against, and the actual profits of wool raising in Vermont, Pennsylvania, Ohio and Michigan, depend so much upon the care the flocks receive, that it is impossible to tell where with a given capital the most money can be made, which in the view of the farmer is the measure of the adaptedness of any district to wool growing. Randal & Youatt on sheep, bound together under the title of "Shepherd's own Book," (price $2.00) is a book to be recommended.

New Book on Grape Culture.—Just as we go to press, C. M. Saxton places upon our table an attractive work on the Garden and Vineyard culture of the Grape, by John Phin. It is very fully illustrated with new engravings, and is intended to supply a great want. We are pleased with it in the main, so far as we have investigated its merits, but of course, before a thorough perusal, must withhold special commendation. In typographical execution, it leaves nothing to be desired in a book of 375 pages and more than 100 engravings, which costs but $1.00. It may be obtained at this office by mail or otherwise.

Prison Life at Richmond.—We have received and perused with great interest, the stirring narrative of Lieut. W. C. Harris, of Baker's California Reg't. who was taken prisoner at Balls Bluff. It appears to have been written in all truth and soberness, and must exalt the patriotism, and warm the sympathies of all who read it. The sketches were written in the famous Tobacco Warehouse, and brought here sewed into the lining of an overcoat. The book is an 8 vo. of 175 pages. Published by G. W. Childs, Philadelphia. Price $1.

Poultry Book.—Fowls are not only very useful and a source of great agricultural profit, but of great beauty, and their intelligent culture is fraught with interest. To poultry fanciers, we can hardly recommend a book more certain to give satisfaction than Bement's American Poulterer's Companion, one of the starred books on our list. Price $1.25.

Chinese Sugar Cane.

The Journal of the Illinois Agricultural Society publishes a prize article on the culture of Sorghum, and its manufacture into syrup and sugar, by E. F. Newberry, from which we extract and condense the following:

The richest soil gives the largest growth of cane, but not the sweetest, and the syrup will rarely grain. Mr. N. found that cane from the post-oak flats, and from the red clay soil near the timber was much superior in richness to that from the black mold of the prairies. Sorghum proved superior to the Imphee, and to keep it pure, it should be planted at least a quarter of a mile distant from broom-corn or "chocolate corn." Seed to be gathered from the earliest patches, should be fully ripe, and only the upper half of each head be planted, as that portion produces the most vigorous canes.

The time of planting varies with the season, but it may safely be put in a week or two before corn. A piece planted the first of March was frozen in for nearly a month, but yielded a good crop of cane, which made a superior quality of light colored syrup. Fall plowing is advisable, repeating it in Spring, and harrowing thoroughly. With abundance of land and scant labor it is better to cultivate in hills 3 feet apart in 4 feet rows. Soak the seed in warm water for 12 to 16 hours and then bury in sacks in the earth until it sprouts. Roll in dry plaster or ashes if it sticks together. Drop 10 to 15 seeds in a place and cover one inch or less. When one inch high, go through with a harrow, having the front tooth removed so that the harrow may go *over* to each row, and follow with the hoe. Continue to harrow, or use the cultivator and tend like Indian Corn, thinning to 5 or 8 stalks per hill when 4 inches high.

Six to ten days before cutting strip off the leaves. This causes the cane to ripen quicker and gives a richer juice. A quick blow with a long wooden knife will strip it rapidly. Do not top the cane until it is fully ripe; then take off the two upper joints with the seed head—and at the same time cut up the cane. There is very little juice in the top of the stalks, and that of poor quality, and incapable of crystalizing.

Cut the cane as soon as the seed is well ripened, and grind as fast as possible. The uncrushed canes may be kept for months if protected from frost by covering or housing, while even a slight freezing, especially before cutting, will give the syrup a bitter, smoky flavor. The grinding mill should be very strong, with two, or better, three rollers—upright if driven by horse power. Let the juice run from the mill through a wire sieve into the barrel or vat. Cook's evaporator is recommended, and a rapid ebullition, using the skimmer, is the best method of clarifying. Boil down three-fourths in the evaporator, and finish in a large shallow oblong pan over a brick or stone arch, into which it is poured through a strainer. Keep up a brisk heat under the finishing pan, until the syrup bubbles like mush, emitting little jets of steam. It is then run into the cooler in a finished state.

To make sugar, reject the upper half of the stalk and boil rapidly, as soon as the juice is pressed out. Pour the thick syrup into large shallow pans or coolers, and stir briskly until cool enough to bear the finger. If it does not begin to grain in a day or two, place in a room heated to 80° or 90°, in open barrels with the lower end bored and plugged in several places. The barrels should stand on blocks so that the plugs can be drawn to let the molasses drain off when the contents have sufficiently granulated.

Important Reports on the Breadth and Condition of the Growing Crops—Reliable Statistics from nearly 200 Counties, Expressing the Opinions of nearly 1000 Farmers.

On page 186 will be found the beginning of an important monthly series of Reports upon the state of the Crops. The Reports this month are limited, but they indicate what is to be done, and how. Owing to the late opening of the Spring, and the lack of requisite time to make up full statistics, not more than half of the reports already provided for are given this month; yet on a single page we have the results of the observations of *nearly One Thousand* persons living in over one hundred and eighty counties, scattered all over the country. Most of those gathering and sending in these reports are intelligent, observing men, who have been designated by Agricultural Societies, Farmers' Clubs, etc., for this special purpose. We feel quite sure that from no other source can so much reliable information be obtained. Next month we shall probably have several hundred reports, but even 200 of them, from different counties, scattered here and there all over the country, and especially in the grain-producing States, will serve as a fair indication of the whole country. We shall still be glad to add to our list competent, reliable men from counties not yet represented.

The reports are very comprehensive, and give in small compass a great amount of statistical information. The numeral **10** is taken for the average, and the comparative surface growing, the condition, etc., expressed in tenths above or below **10**. [See explanations over the reports.] At the end of each column is a general average, obtained by dividing the sum of all the reports under any head, by their number.

SUMMARY FOR THE WHOLE COUNTRY.

A—The Weather averages nearly 9, or a little below the average of other years (10)—taking into account its effects upon winter grain and fruit, and upon general farm operations. The notes accompanying the reports speak of the weather as very backward, retarding spring work, etc., but first-rate for winter grain and fruit.

B—C—Of Winter Wheat, the breadth growing averages fully a tenth more than in 1861, and fully one-third more than the average annual breadth, for a period of several years.

D—The general prospects of Winter Wheat promise one-third above the average yield.

E—F—Spring Wheat.—The surface sown this year averages one-tenth more than last year, and eight-tenths more than the average annual breadth for five years past.

G—The prospects for Spring Wheat are not quite equal to the average of other years.

H—I—K—Indian Corn.—The planting was not far enough advanced on May 10th for those forwarding reports to give full statistics, though many reported the probable number of acres planted and in preparation. These indicate a surface about equal to last year, but a third more than the annual average for five years past. Much fuller statements will appear in the monthly reports hereafter.

L—M—Rye.—Surface sown, nearly the same as last year. Prospects a tenth better than usual.

N—O—Oats.—Surface sown a little above the average, and prospects nearly an average.

P—R—Hay Crop.—Breadth growing and prospects, rather above the average.

S—T—Potatoes.—The surface planted fully an average; prospects rather poorer than usual.

U—V—Fruit.—Reports almost universally good. The average indicates a double crop of apples for the whole country, and a threefold crop of peaches. These are more indefinite estimates than will be furnished next month.

GENERAL AVERAGE.—The general average of all the figures given in our tables, including surface, prospects, etc., is **12.6**, or one-fourth better than the average of other years. This is more favorable than we had anticipated, until we received and compiled the reports and read the notes accompanying them.

A Change—The Michigan Farmer.

The *Michigan Farmer*, hitherto published at Detroit, is now merged into the *American Agriculturist*. Subscribers who have paid in advance for the *Farmer*, will receive the *Agriculturist* for the *full time* paid for. The services of Mr. Doty, recent Editor and Proprietor of the Farmer, are secured for the *Agriculturist*, and his P. O. address is now at this Office. His former patrons will thus continue to receive the benefit of his labors, and in addition, the advantages of the *Agriculturist*, with its larger facilities, and yet at no advance in the annual cost.

The above is the *seventh* Agricultural Journal merged into the *Agriculturist*, during the same number of years. A friend inquires how long, and how far, this absorbing process is to go on? We answer, just so long as publishers of other journals continue to find it to their own interests, and to the interests of their readers, to propose such changes, if on terms we can afford to accept. No proposition has ever been first made by the proprietor of the *Agriculturist*.

Let us here remark, however, that there are some manifest advantages in this merging process—to the readers, if not to the publishers. For example, the Connecticut *Homestead* was a good paper, and so was the *Agriculturist*, as all admit, we believe; but the *Agriculturist* now has the combined, earnest efforts of the editors of both papers, with no addition to the subscription price. The same may be said, in part, of the union of other papers with this. New York is a central point, almost as accessible, and as directly connected with most sections of our country, as their own capital towns. This may, therefore, well be the central point for issuing a leading journal for all parts of the country. The average circulation of 25 out of the 30 agricultural and horticultural journals in this country probably does not reach 3,000 copies. The circulation of the *Agriculturist*, for sometime past, has ranged from **60,000** to **88,000** copies. Is it not better to combine the efforts of twenty men upon *one* such a journal, than to divide them among *twenty* or *thirty* of 3,000 circulation, each requiring all the office machinery, etc., and necessarily requiring the paying of twenty or thirty subscriptions by any one desiring to avail himself of the advantages of the whole? This concentration of effort at one point has one disadvantage, and one only, viz.: that local matters—of Societies, Fairs, etc.—can not *all* receive constant attention. But the local political and news journals will, in a measure, afford facilities for giving local news, while a few leading agricultural and horticultural papers, at principal points, can furnish the required amount of strictly agricultural information of general interest. We hope the time will soon come when every State shall support at least one first class journal, devoted to the great farming interest; and were farmers sufficiently awake to their true interests, this would be done at once, or as soon as the right men could be found to conduct such journals. But for the time being, it seems a waste of effort to try to keep up one or more vigorous, first class agricultural journals for each locality.

Tobacco Cultivation—No. IV.

Tobacco culturists have now plowed the land deep and turned under a liberal supply of barn-yard manure, and for two, three, or four weeks, the ground has lain exposed to the sun and rains. The influence of these has been very important. The soluble ingredients of the manure have become diffused through the mellow earth, inducing decompositions in the soil itself and rendering still more plant food available. The weathering has a similar effect; in fact, the ground has had a good fallowing with all its beneficial effects, so long as it remained in this condition. Weed seeds germinate under the influence of the May rains, and the rawness of the freshly upturned soil is thoroughly cured.

Were we to prepare a piece of land for tobacco, after proceeding as directed in the May *Agriculturist*, according to the amount of manure then plowed in, or incorporated with the surface soil, we would add more or less. A good surface dressing of well rotted stable manure or fine compost, might first be spread, (unless the land were to need harrowing once or twice to kill the weeds,) and directly upon this we would put 10 to 20 bushels of unleached ashes, three to five hundred weight of gypsum and three or four bushels of salt to the acre, (in the absence of barn-yard manure we would use about 200 lbs. of Peruvian guano of the best quality); and it should be immediately plowed under very shallow, but not so as to interfere with lightly harrowing it; which done, it should be rolled and marked out for planting. Set the plants in rows three feet apart and two feet and-a-half to three feet distant in the rows.

At the very first of this month the seed beds should be looked to, and the plants quickened, if at all backward, with guano water or other liquid manure, so as to be ready for transplanting as soon as the 15th. It is hardly worth while to attempt to transplant tobacco earlier than the middle of June. For some ten days or a fortnight after they are set they are peculiarly exposed to the attacks of the grubs and cut-worms, and they are only free from this danger when they have begun to grow very vigorously; this time comes when we have steady *hot* weather. It is a good rule to be ready to transplant on the first rainy day after the 15th of June. Care must be taken in transplanting; the plants being handled much like cabbage plants, and the smallest of them should have three or four leaves as large as a silver dollar. If the sun comes out hot the next day, mow a few swaths in short thick grass, wet it thoroughly, and use it to cover the plants. Cut hay or straw will do, but is not so good. Keeping a good watch of the plants every morning, the cultivator will see at once any one wilted or drooping, and will often find the worm at the root, and he will replace the plant thus destroyed at the earliest possible moment. Move the plants with a ball of earth attached that they may be less put back and that the field may be more even in appearance. After the plants become well rooted the field is tilled regularly, being hoed and weeded like corn, using the horse hoe or cultivator.

Ladies on Horseback.

Learning that our article on Saddle Horses, a few months ago, interested many, and was the occasion of benefiting several invalids, the writer will now present a few hints on female equestrianism. As a mere accomplishment for young ladies, it ranks high. Perhaps in no place do female charms appear more fascinating, than in the saddle. You may think it is the jaunty cap and plume our Belle wears, or her flowing dress, or the fresh color which riding brings into her cheek, and the sparkle it gives her eye; you may say it is the spirited motion of her palfrey, or the contrast between his rugged strength and her delicate beauty. Analyze it as you please, it will yet be confessed, (certainly by every young man open to conviction) that Belle never looks so charming as when on horseback. We have heard of more than one susceptible youth who has lost his peace of mind by witnessing such a sight. Indeed, to old or young, it is very pleasing. And then, if to this sight you add several young ladies and gentlemen in different colored dresses, prancing along the highway together, you make a picture worth looking at.

The healthfulness of this exercise, few will question. It tends to give a young lady an erect posture; it strengthens her arms, chest, limbs; expands the lungs, gives tone to the stomach, and clearness to the brain. If the digestion is impaired, it will restore it much quicker and better than pills or bran-bread. The fine effect it has upon the spirits is enough to recommend it. How much more enlivening it is than rolling luxuriously over a smooth road in a modern, spring-seated, close-covered, velvet-cushioned carriage! Yet, many of our sighing young misses prefer the latter, 'it is so much more refined!' They think their complexions of satin softness and lily whiteness, would suffer from the exposure of horseback riding! Did you but know it, young lady, nine out of ten young gentlemen would be more pleased with you, if your complexion had the healthier tinge that comes from vigorous exercise in the open air. Who has not known or heard of invalids so weak that they had, at first, to be lifted into the saddle, but who, by steadily pursuing horseback riding for a period of weeks and months, have recovered vigorous health? All of us have known invalids with pulmonary affections, who, having tried the prescriptions of doctors of every school in vain, and having traveled to the sunny South to little purpose, have at last resorted to the saddle, and gained therein more advantage than from all things beside. Many a lady needs out-door exercise, but is too feeble to walk a great distance. Mount your horse, then, not your luxurious carriage. Mount your saddle, and you will find your weak back strengthened, your nerves braced, your head-ache dissipated, and every part of your system toned and invigorated. Your horse will do the hard work for you, and yet give you all needful exercise. He will bear you over the hills and far away into the woods, to gather flowers, and see the birds, and if you like, down yonder gorge to see a waterfall, and over the bridge to a certain farm-house to visit some friend, and see her pleasant occupations. Wherever you will, you can ride, and then come home refreshed and inspirited with new health. In England the ladies ride horseback more than in the northern United States. It often forms a part of their education to learn to sit in the saddle gracefully, and to manage a horse with skill. In the southern states of this country, it has long been a very common practice. The writer of these lines has often raced with Virginia lasses, leaping brooks and ditches, and low fences, side by side with them, and he confesses that he generally (gallantly?) came off second best in the contest—as in duty bound. We are happy to know that female equestrianism is becoming, of late, more popular among us. In many of our cities, riding schools have been established, and along our parks and broad thoroughfares, many a gay company of lady-riders can be seen almost any fair day. So too in the country generally, there is an increasing fondness for this exercise. *

Halter Breaking Young Colts.—There is as much advantage in beginning early with a colt as with a boy. It is serious business to most farmers to break a stout four year-old to the halter, and to handling; but begin with a sucking colt, and you have an easy task. He takes gentle handling kindly, may soon be made familiar with the halter, and do your bidding. After a little training, the boys can lead him to the pasture and to water, which will be a good lesson for them, as well as the colt.

Concerning Old Horses.

Not those *very* old hacks, on the shady side of twenty. Not those broken down with hard work, "lame in one leg and blind in one eye." No: we simply mean horses that have got over their youthful follies, and settled down for life into good, honest, staid habits. In age, they may range anywhere between eight and fifteen years; for if they have been properly used, they are not old, in a bad sense, until they have passed this limit. All along through this period, such an animal may be styled our "good old horse," our "safe family horse," and other fond epithets. Who does not like such a beast? Your hair-brained youth, full of daring and lusty strength, may prefer an animal as wild as himself. Horse dealers and fast men may like one that will never allow another to pass him on the road, even though he starts at every strange object in the street—one that prances and paws and chafes under restraint; but sober and sensible men have very different likings. They want a horse that, while he has abundance of spirit, is, at the same time, easily restrained; that does not fret and worry at his work; that carries his rider, or draws his load cheerfully, steadily, vigorously, until his task is done. Your old horse does this. Let him stand idle a day or two, and he will play like a colt. Have a care, or he will dance you out of the saddle. Look sharply, or he will make the old family carriage whirl, and give the ladies a harder jolting than they desire. But ere long he sobers down, and saves his reputation as the "good old horse."

The horse and his master are generally in keeping. The man has sown his wild oats, is married, and has a household to provide for; can't waste his time and strength in exciting follies, and don't wish to expose his family to danger. So he buys him a good old horse, one that can always be relied on, one that has at least $20 worth of *stand-still* in him. Animals like these deserve great respect and consideration. They are the most useful citizens in horse-dom. On them the burdens of life chiefly rest. They manifest a deal of sober dignity, as if conscious of weighty responsibilities. It is painful to see such horses over-driven or overworked in any way. Of course, they are not as quick as they once were, yet they will work over about as much ground in a day as most young horses, if they be allowed to go at their own pace. They should not be over-strained with heavy loads. Give them reasonable burdens, let them move moderately, and they will work faithfully day after day without flinching. Such horses should have some special care in feed and grooming. Adapt the treatment to their

wants, and they will continue useful many years after they would otherwise have been laid aside. A writer in the Ohio Farmer well says that "the last part of a horse's life may be more profitable, if rightly used, than the first part. There is more comfort and less danger in working old horses. We understand them, and they understand us, and we should be as willing to conform to their nature, as they to conform to our wishes. It would be more humane, as well as more profitable, to use them as they should be, as long as it would pay, and then take them out and shoot them down. But the practice of many is to knock them about as much as they will bear and pay well, and then trade them off to some more inhuman wretch than themselves."

Cost of Keeping a Horse.

In the March *Agriculturist* a request was made for information on this subject, and we have received several responses which are interesting and instructive. W. M. W. of Middlesex Co., N. J., reports the expense of keeping one horse (worth $130,) for 1860 and 1861, as follows:

1860.

23½ bushels of corn at 72½c. per bushel	$17.04
33½ bushels of oats at 37c. per bushel	12.47
3631 pounds of hay at $15.14 per ton	44.24
Shoeing,	2.54
Total cost for one year	$76.29

1861.

15 bushels of corn at 60½c. per bushel	$9.06
26½ bushels of oats at 32c. per bushel	11.79
3500 pounds of hay at $13.33 per ton	36.68
Shoeing	2.45
Total cost for one year	$59.98

R. G. of Warren Co., N. Y., reports as follows: I have kept horses for the last 40 years, and find that the expense varies much according to the use, or labor required from them. A horse can be kept in ordinary order for doing light work, and nothing more, on the following:

1st 6 months—2 tuns of hay at $6 per tun	$12.00
" 45 bushels oats at 50c. per bushel	22.50
2d 6 months—1 tun hay	6.00
" 12 weeks pasturing at 25c. per week	3.00
" 45 bushels oats at 50c. per bushel	22.50
Shoeing for the year, $6; Grooming, $6	12.00
Depreciation 10 per cent., and interest 7 per cent	17.00
Total cost per horse for one year	$95.00

Samuel Simpson, New-Haven Co., Conn., writes: "I have kept from one to three horses the past 26 years, part of the time owning land, and raising their feed; but will give a statement of the expenses for two horses kept from May 1856 to May 1861, five years, during which time I bought all their feed. They consumed about

5 tuns of hay annually, at $15 per tun	$75.00
200 bushels of oats at 50c. per bushel	100.00
1 tun of straw for litter	6.00
Shoeing	10.00
Add interest on $300	18.00
Total	$211.00
Sold the manure annually for	20.00
Net cost of the pair per year	$191.00
Net cost of keeping a single horse per year	95.50

During the whole 26 years I have never had a horse die, and in a majority of cases have received more than I originally paid, when I disposed of them. As a general thing I have driven my horses myself, and have been careful to see that they were well taken care of."

These accounts and estimates show very nearly the cost of horse keeping, at the different prices of provender specified. It is proper to add the interest on the cost of the horse, and the depreciation, where these items are omitted. Ten per cent will not more than cover the risk, and depreciation, taking the average. It would have added to the interest of these statements, if the weight of the horses had been named. It usually costs more to keep a heavy horse than a light one, and for many purposes the light horse is the better animal. This item of economy is generally neglected, but worth looking after.

Unruly Milch Cows.

It is no wonder that some cows are fractious, they are treated so roughly. Why kick, pound, and bawl at them? It only makes matters worse. It makes the timid ones shyer, and the spirited ones ill-natured. We urge kindness not only as a matter of humanity but of profit and patriotism—aye, profit to your heart, profit to your pocket, profit to your country. It is vain to try and whip or frighten a cow into quietness and docility. So treated, she dreads and hates to see the milk pail and stool coming, and will prepare herself for a battle. How can she stand patiently and give down her milk, while expecting to receive hard thumps?

Suppose her to be treated kindly—a little salt or some other relish given to her a few times, kind and soothing words spoken, and a little caressing made with the hand. If somewhat restless at first, keep your temper, and follow her up with daily kindness. The result will surely come. She will soon know what to expect from her milker, and will show her likings by unmistakable signs. No person who can not control his passions, and speak low, and be always gentle, should be allowed to milk a cow. It is of importance, too, to milk at regular hours. There should seldom be a change of milkers.

A successful dairyman once observed to an agricultural editor, that one of the secrets of his success lay in the kind treatment he gave his cows. They were driven to and from the watering place, leisurely. No dogs were allowed to distress them. No hired man was suffered to beat or to scold at them; whoever did so, was discharged at once. The cows were well fed, and allowed to take their own time in all their movements, especially in warm weather. Being so treated, and milked regularly and clean, he believed that from fifty to a hundred more pounds of cheese could be made per season from each cow, than if they had been kicked and frightened, and otherwise roughly handled. *

Diseases of Calves—Scours.

At this season, the most common and often fatal disease of young animals—colts and lambs as well as calves—is the "scours" or diarrhœa. It manifests itself in two forms, the white, and the yellow. The white scour, as the white is generally called, is caused by indigestion and the decomposition of milk in the stomach; the yellows, by an excessive flow of bile. A heavy damp state of atmosphere is particularly conducive to the generation of this disease. In localities where the land is either low, wet, or badly drained, or subject to be flooded, the attacks are always characterized by greater severity. Some particular grasses, the changing of the pasturage of the mother from a dry upland to either young clover or to low meadows, the removing of the calf from the care of the mother to a strange cow, feeding the calf on stale scalded milk after the cream has been taken from it, without adding a corrective substitute for the essential principles so abstracted, all exercise an injurious influence on the health of the calf by causing relaxation of the bowels or scouring, which, if suffered to continue unchecked, will inevitably result in the loss of the animal; nor is exposure of young calves, and other animals, to wet or cold weather less fatal in consequences.

The disease, if taken in time, is not of itself dangerous—death, in most cases, resulting from the extremely emaciated condition to which the system of the animal is reduced for the want of proper care, in due time. "An ounce of prevention is worth a pound of cure;" therefore, the rearers of young stock should provide good, *dry* pens for their calves, especially those intended for the butcher, and, with respect to those set apart for rearing, they should, whenever the weather will permit, be turned out during the day into a well shaded pasture, taking particular care to house them *early*—before the dew falls.

The treatment of this disease, in its early stages, as a rule, is confined to very simple remedies; *first*, administer ½ oz. of Epsom salts with a very small quantity of ground ginger, dissolved in a little fine flour gruel; by this means the stomach and intestines are cleared of all foreign or acrid matter. After allowing time for the medicine to operate, (8 to 10 hours,) give the following: Prepared chalk, 1 oz.; extract catecheu 2 drachms; opium powder, 1 drachm; peppermint water ½ pint; one tablespoonful three times a day. It will rarely be necessary to continue the use of this mixture for more than two or three days. In cases of great prostration and debility, tonics and stimulants should be given without delay; in such instances give: tincture gentian, 1 oz.; essence of ginger, ½ ounce; peppermint water, 4 ounces; one tablespoonful twice a day. During the time that the cases are under treatment, good, well boiled wheat flour gruel should be given twice a day. This will also often check incipient diarrhœa without the use of other medicines. *

A "Commentary" on Roots.

By Timothy Bunker Esq., Hookertown, Conn.

"I should like to know what upon airth you dew to your cattle to make 'em look so slick?" said Jake Frink as he looked into my yard on a bright April morning.

"Dew to 'em, you fool," exclaimed Tucker, "he stuffs 'em with ile meal, and corn, just as you would a sassage."

"I'm mighty glad I don't have the bills to pay," said Jones. "That animal has cost fifty dollars this winter, I'll bet a shad; and 'twouldn't sell for that neow." "Don't be so sure of that," said Seth Twiggs, as he joined the company at the gate, and looked admiringly at Cherry, who had dropped her third calf a few days before. "I am in want of a new milch cow, and will take her at that price without the calf."

"You will have to add ten more to get her, I guess, even if I want to sell," I remarked very quietly, as I showed a pail half full of milk after the calf had taken all he wanted to suck. "But you see I never sell a new milch cow. Making butter and cheese is my business, and milk is my stock in trade. A shoemaker might as well sell his leather, or a tanner his hides, as a farmer sell a new milch cow. The dairy farmer, who has his eye teeth cut, will sell cows only when they are well fattened, or at the close of the milking season."

"But s'pose he has mor'n he wants," said Seth inquiringly, as he loaded his pipe.

"He has no business to be in that fix," I replied. He raises a given quantity of hay, and rough fodder, corn stalks, straw, pumpkins, roots, etc., and he ought to know just how much it will take to bring them out in good condition in the Spring. If he has only fodder enough for twenty head of cattle, he makes a great mistake if he keeps twenty one, and is foolish if he attempts to keep five and twenty. With food enough, he will make a profit on each; with too little, he will loose on every one."

"'Loose *every one*,' you ought to have said,"

interposed Seth, with a knowing wink at Jake Frink for his recent experience with the horn-all.

"Cherry," I continued, "is what I call a living *commentary on roots*. Mr. Spooner has a good deal to say about the opinions of different commentators on this and that text from which he preaches. I always thought that the best commentary on a man's faith, was his *practice*. His life shows well enough what sort of food his mind lives on, and it is pretty much so with fodder. There's a good deal of truth in the old adage 'The proof of the pudding is in the eating.' The kind of pudding my Cherry has lived on all Winter is turnips, sugar beets, and good hay. Not an ounce of meal upon the honor of a gentleman, and she gave milk until within two months of her calving. You see, now, she is as sleek as a mole, with a bag as big as a milk pail, and a fine calf."

I put the ease to my neighbors, Mr. Editor, in that way, and made them see it. I know a good many farmers say roots don't pay for raising, that they are all water when not frozen; and if they are frozen, you might as well feed your cattle on snow banks. I know that the chemists say that they are more than three-fourths water, and not worth half as much as hay, which may be true enough. But what do I care for these opinions, so long as roots make flesh and milk cheaper than any thing else I can raise. I am after milk and flesh by the cheapest method, and if giving water to the stock will bring them, I shall give them water—Jake Frink, and Mr. Retort to the contrary notwithstanding.

White turnips stand particularly low in the scale of nonrishment, and yet Cherry had white turnips, a half bnshel a day, until they were all gone, and gained flesh upon them. She did better on sugar beets; and for that reason, I think they are worth more, and if they could be raised as cheaply as turnips, I should prefer to raise them. But I do not see how they can be. I can raise turnips among corn, as a stolen crop, for four cents a bnshel, and I think all roots that require a whole season—beets, carrots and parsneps—will cost not far from ten cts. a bushel.

My rule is to raise all the roots I can, of the several varieties, so that every animal may have a daily feed of them from November until May. They like a variety of food, and with hay as a staple, I think the greater variety the better, feeding say two weeks upon one kind, then taking another two weeks. Many think they can get more fodder from an acre of land in grass or in corn, than in roots. Not so:—An acre of land has to be highly manured to produce seventy bushels of shelled corn, and four tuns of dry stalks—worth at the market price not far from a hundred dollars, which is perhaps a fair expression of their value for feeding. The same acre, with rather more labor, will produce 1000 bnshels of carrots worth from two to three hnndred dollars in different markets, just as their value is known and appreciated. I have raised all the roots usually cultivated for feeding, and I come to the bottom of the root bins every Spring with a stronger conviction of their value. *The living commentaries* tell the story a great deal better than I can, and some of my neighbors have got the lesson. Deacon Smith learned it before I did. Mr. Spooner got hold of it early, and he always drives a fat horse, that goes round the parish preaching carrots, wherever he calls, just as plainly as Mr. Spooner preaches election in the pulpit. Now I have nothing agin Mr. Spooner in the world, and I don't mean any reflection on him when I say that the old horse has more "unction" in his preaching than any thing we have in the Hookertown meeting-house on Sundays. There hasn't been a rib in sight since he has owned him, and when he drives up to the door on Sunday morning the horse comes up with a praneing gait, and a coltish air, that says "carrots," as plain as if Mr. Spooner had a bag of them under his carriage seat. I don't talk such things Sundays, but you know a man can't help thinking.

And there is Seth Twiggs, whose brains one might think were all smoked out, has got ideas straight as a ramrod on roots, and raises heaps of them every year, though he has but a few acres of land. Even Jake Frink is waked up by the preaching of Mr. Spooner's horse, though he never hears the man—except at funerals. He goes in for a crop of sugar beets this season, for the first time. Tucker and Jones are not yet converted, but I am expecting even they will be brought in before long.

One of the advantages of the root crop is, that it may be put in late. Rutabagas and carrots may be sown without any detriment any time in the month of June; white turnips a month later, and the first week of June will do very well for sugar beets and mangel wurzels. This last is the most productive of all the roots, and but little inferior to the sugar beet in quality. The "commentaries" on roots are multiplying here.

For the American Agriculturist.

Rocky Mountain Farming.

BY A COLORADO FARMER.

Our climate here is generally the most delightful I have ever experienced. Our rains are periodical and of short dnration, say abont four weeks, commencing the last of June and ending the last of July. In the mountains the rainy season is longer. The atmosphere is light and dry, the nights cool, the days warm. During the Summer of 1860, we had no warm nights—all cool enough to bear a good comforter—but the Summer of 1861 had all comfortably warm nights. The former year developed no mosquitoes—the latter produced multitudes. Last season we had but little frost in April or May, none to hurt lettuce, radishes, and hardy vegetables. But little snow falls in the valleys dnring Winter, and we have but few days of severe weather. The cold snaps usually come from January 1 to 15, but sometimes either earlier or later. September, October, November, and December, except a few days, are pleasant beyond any thing I ever experienced elsewhere. Our warm weather in Winter does not produce lassitude; the atmosphere is clear and bracing. Except on the highest, or Snowy Range, little snow falls in the mountains, where the most of the quartz mills are running, and that little does not lie long, except where drifted in valleys. The changes from hot to cold are not greater than I have always experienced in the North, East, and South. Vegetables have been drawn into the mountains all Winter so far; at no time has the grass been covered by the snow. Our cattle have been unhoused and are fattening finely. This Winter is milder than last—about like that of '59 and '60, and a fair average of the winters in this climate.

Severe and killing frost comes September 14 to 17, uniformly—in three Falls it has not varied from these dates; then follows the most beautiful fall weather I ever saw. Certain warning is given to secure all perishable products, and ample time to save fall crops. We have an occasional hail storm; severe blows, with cloudless skies, and sudden changes of weather; we have dry roads all the year—the best natural roads the world ever saw—and general freedom from colds. With proper care this is certainly a healthy climate. But we have yet no system, no care, and few of the comforts of our former homes. As the country improves the little sickness we have will greatly diminish; and I am satisfied our mineral springs, mountain ranches, and country seats, will be the resort of invalids of other climes. Exposure and neglect, with improper diet produce scurvy, fever and rheumatism, with an unusual amount of erysipelas; all which yield readily to proper treatment. Among the prominent causes of diseases may be counted the universal and immoderate use of soda in cooking. Yeast bread must remain a scarcity until the supply of women is increased.

Soil.—Our valley soil is composed of sand, ashes, and decomposed vegetable matter. Most of the tillable land lies in the creek valleys, though there is much of the high lands on the divides, [elevated land between the creeks or "forks,"] which can be made highly productive by the application of water; these uplands have more clay, less sand and decomposed mountain vegetable matter. What we call willow land on the bottoms is very rich and productive—yielding 200 to 400 bushels of potatoes per acre. The soils in the valleys vary from 6 inches to 4 feet in depth, the whole being regulated by the irregular action of the streams in changing their channels in past ages. The bottoms of these are uniformly covered with bowlders and sand. The mountains yield an annual supply of ashes from the burnt districts, which can be rendered useful by irrigation. Our larger valleys, further from the mountains—such as the Platte—have fewer bowlders, and more rich tillable land. When our lands are brought fully into use we shall be able to support a large mining population, and raise nearly every thing we want.

Capacity of Soil and Climate.—Wheat, rye, oats, barley, corn (early varieties), vines (cucurbitous) of all kinds; roots of all kinds; in short, nearly every thing produced for the New-York market can be raised here in great perfection. Sorghum and Imphee cane have both been successfully produced. Sugar beets would attain prodigious size. I have raised Kidney potatoes weighing 1¼ and 2 pounds; other varieties grow much larger than in the States. Cabbages 20 and 24 lbs.; pumpkins and squashes enormous, and finely flavored—say 60 to 100 lbs., and fine grained, splendid for table use. Beets, turnips, 8 and 12 lbs. Wheat 35 bushels per acre without irrigation—will probably reach 50 with proper culture. Flat turnips and rutabagas, yield immensely. Hungarian grass also does well. These items will give your readers an idea of what the natural soil will do. The results of manuring, this deponent will not calculate. Potatoes, onions, turnips, and kindred plants, come to perfection even in the mountains.

Fruits.—I fear we shall not be able to raise fruits. Our warm days and cool nights, Spring, Fall, and Winter, will render all tender fruits uncertain, provided there be no other difficulty; the shortness of our seasons will enhance the obstacles. A few fruit trees are planted in this vicinity. On the Arkansas, which rises in the mountains, my brother has started a fine peach orchard which will soon test the southern part of our Territory, and as soon as may be, I shall test this section. Time will likely point out favorable spots, on north hill-sides, and at the base of the mountains—perhaps in the Canons (kan-yons)—where fruits may be successfully grown.

JOHN B. WOLFF.

Fig. 1.

How the Sap Circulates in the Trunks of Trees.

In the town of Yonkers in this State, a few years since (in 1855), after a severe winter, the bark of some six or eight trees in a young orchard was found split down perpendicularly. The trees were not properly attended to, by binding the bark to the trunks and closing the cracks with cement of some kind. In the course of the summer they all died but one. This tree lived and flourished; the bark, however, separated from the trunk and formed a roll upon one side, being attached to the sound parts of the tree above, and to the root below. Fig. 1, represents the appearance of the tree at this period. The edges of the bark grew together and wood was deposited on the interior of the roll. The second year it flourished, the bark trunk becoming firm and woody, and the third year it fruited, the naked trunk decaying rapidly, so that it was necessary to support the top artificially. Finally the old trunk decayed altogether, and the tree, when we last heard of it, presented the appearance shown in fig. 2. In this interesting case we have a demonstration of the received doctrine in regard to the functions of the wood and bark. The injury to the tree having taken place in the winter, the sap wood through which the sap rises in the spring was still capable of performing its functions. The sap ascended through the naked trunk, was elaborated in the leaves, and returning, it passed down the inner film of the bark, depositing the new inner bark and young wood within the bark roll, much as if nothing had happened. By the time that the action of the weather had dried and unfitted the old trunk for a sap channel, there was a new channel already formed within the bark, showing most conclusively that the new wood is a deposite from the bark and independent of the old wood.

Fig. 2.

PEELING APPLE TREE TRUNKS.

There is a practice, precisely the reverse of this, sometimes employed to give old apple trees new bark. It depends upon the fact that when the new bark and the new wood are first formed, they are easily separated from the bark, by which they are deposited, but adhere more firmly to the wood. If about the 20th of June the bark be removed from an apple tree without injuring the trunk (which will appear entirely naked, but is in fact covered with a delicate tissue, conducting the sap as it descends,) a new smooth bark will rapidly form. The time at which this is performed is very important, as a few days too soon or too late makes the operation a fatal one to the tree. We have known trunks of trees which were called hide-bound, or bark-bound, the bark of which was full of insects and covered with moss, thoroughly cleaned, and by this process clothed anew with the smoothest most beautiful bark we ever saw. The general health and condition of the tree was greatly improved, so that they responded to manuring and became again fruitful. We can not, however, recommend the practice, as it seems hazardous and may be so in reality. *

The Buffalo Tree-Hopper the Cause of Scars on the Twigs of Fruit Trees.

By Asa Fitch, M. D., Entomologist to the N. Y. State Agricultural Society.

To the Editor of the American Agriculturist.

From the cuttings of cherry twigs which you sent me, and from information which I previously possessed, I draw up the following account of a malady in the twigs of fruit trees, of which no published notice has hitherto appeared, that I am aware. In Winter or Spring a peculiar kind of crack or scar is sometimes observed on the twigs of apple, cherry and other trees. It extends lengthwise of the twig and is from ¼ inch to 2½ inches long. It occurs on twigs that are nearly or quite ¼ inch in thickness, and two or more of these scars are frequently seen along the same twig. Their surface is slightly elevated above the level of the bark, has a rough, cankered appearance, and shows a deep crack along its middle, in which crack a row of small holes is more or less distinctly to be seen, extending the whole length of the scar. On splitting the twig it is seen that these holes are bored down into and almost through the soft pith in its center, in a slanting direction, and that each hole is somewhat bent or curved and is occupied by the egg of an insect. The eggs are shining, yellowish white, cylindrical with rounded ends, and four times as long as thick—their length being a little more than the tenth of an inch, and exactly filling the holes for about two thirds of their length. In a scar 2½ inches long I count 55 eggs. And now, what insect is it that makes these wounds?

Buffalo Tree-Hopper.

Some years ago I found willow twigs in my own vicinity wounded in this manner, but the holes in the scars were empty, the insects having hatched and left them. In the Spring of 1858, the twigs of apple trees at Akron, O., were very much injured in some orchards by wounds of the same kind. The malady excited the attention of H. W. Howe, Counsellor at Law, of that place, who sent me specimens of the wounded twigs, and some correspondence thereupon followed between us. On learning how much of a novelty these wounds were, and that the insect making them was unknown, he devoted particular attention to this subject, and at length was so fortunate as to detect the culprit in the very act of piercing these holes, and specimens of it were thereupon sent to me. It is thus to Squire Howe that we are indebted for knowing what insect it is which causes these wounds and the manner in which it makes them; and in justice to him I ought, ere this time, to have made his interesting discovery known to the public. This insect is so common through the northern States and Canada, and has such a peculiar form that it has at some time been noticed, probably, by every person who has his eyes open. It begins to be seen soon after the middle of July, and remains until the end of the season. It is from three to four tenths of an inch long, of a light grass green color, freckled rather faintly with whitish dots, and is *shaped like a beech nut*, with two short sharp-pointed processes, like horns, jutting outward in front, one on each side, giving its forward end some resemblance to that of a bull or buffalo. Hence it has received the name of the Buffalo Tree-hopper, or *Ceresa bubalus*, as it was scientifically named originally by Fabricius. It pertains to the Homopterous division of the order *Hemiptera*, and to the family *Membracidæ*. This insect may frequently be seen standing on the small limbs of the apple-tree, the locust, and other trees in our orchards and yards, with its head towards the base of the limb. It remains perfectly motionless and quiescent; but if the finger approaches it, with a sudden strong spring it darts away with such velocity that the eye is seldom able to follow it, or even perceive the direction in which it has thrown itself.

A twig wounded by Buffalo Tree-Hopper.

The piercer, lancet, or ovipositor—the instrument with which the insect perforates the holes in the twigs—closes into its sheath, much as the blade of a pocket knife does into its handle. It is plainly to be seen thus closed in a groove, which is at the hind part of the body on its under side. To perforate a hole, this piercer, as Squire Howe informs me, is held obliquely downward and forward, or like a knife blade a quarter opened. Being in this position and with its point pressed against the bark, it is by a forward movement of its body that the insect draws or thrusts it downward through the bark and soft wood and into the pith. An egg, no doubt, is then passed into the perforation, as the implement is being withdrawn. The wounds which are thus made are scarcely perceptible at first, but become more and more conspicuous with age. It was the last of September when Squire Howe discovered the insect at this work, and some of the wounds then on the twigs he judged from their appearance had been made a month earlier.

The eggs remain in the twigs through the Winter and hatch in the Spring. They do not produce worms, but small active insects which have some resemblance to the parents in their shape, though they are destitute of wings and of the hard shell-like covering which they acquire when they become fully grown. They wander away from the twigs as soon as they are born.

Both the young and the perfect insects nourish themselves by puncturing and sucking the juices of the leaves or of the new tender bark of the twigs. They are thus pernicious to the vegetation on which they occur, as well as by wounding it to insert their eggs. And in seasons when these Tree-hoppers are noticed as being so common as to excite fears of injury to our fruit

trees from them, it may be well to occasionally shake or jar the trees to frighten off these insects—for I think few of them will remain on trees where they find they are liable to be thus disturbed, but will fly away from them to some of the forest trees, which appear to accommodate them as perfectly as do the fruit trees.

For the American Agriculturist.

Experience in Hoeing Wheat.

A few years past I have been trying some experiments in tilling fall wheat and other winter crops—in the Spring as soon as the ground is in condition to stir, say about the last of April and first of May—with decided beneficial results. When the wheat has been sown in drills, it can be hoed with a pick, or broad hoe, if desired; and if sown broad-cast, the ground may be mellowed up with the pick hoe or a sharp stick. It will not injure the wheat if covered a little with earth when small, nor if some of the roots are broken, any more than it will corn. Wherever I have tried the experiment, the difference in yield was very great, the straw being longer, the grain longer kerneled, and heavier per bushel. Heavy soils want mellowing more than open lively soils, and they will bake in the sun unless loosened up by some hoeing process. Those stools that were injured by the winter are strengthened by the hoeing, and branch out, or "tiller," vigorously, while feeble plants become large and healthy. At the same time, all foul stuff that comes up promiscuously among the grain may be removed, letting in light and heat, and the influence of the atmosphere.

I believe thorough tillage on heavy soils will add 25 to 50 per cent to the crop. The hoeing of wheat by hand in this country is rather slow, and it will not pay very well. I have rigged a cultivator with small teeth, on wheels, to follow between the rows, and by the use of handles can guide the teeth between the rows of wheat, to fit any curve that the drill may have made.

I am not making any of these cultivators, but if any person wishes to try the experiment this season, he is welcome to get one up, and I will give all necessary information. A. B. TRAVIS.

Brandon, Oakland Co., Mich.

OXFORD, Mich., Sept. 21, 1861.

This certifies that in May last Mr. A. B. Travis, of Brandon, cultivated a few rows of wheat in a field of mine [with his wheel cultivator] as an experiment; the rows of wheat were easily traced with accuracy, leaving the ground mellow and clean, and without the least injury to the wheat. At harvest I found [estimated] the cultivated wheat 25 to 30 per cent better than that on either side that had not been cultivated, but otherwise had an equal chance. Another year I shall try the cultivator more extensively, and I confidently recommend it to all wheat growers. DAVID G. DUNLOP.

We were present when Mr. Travis cultivated the wheat for Mr. Dunlop, and assisted in harvesting the same, and cheerfully testify to the correctness of his certificate. (Signed by) HENRY VINTON, M. J. DUNLOP, S. VINTON.

Connecting Links.

Links of the form which we represent are exceedingly convenient if at hand when a chain happens to break, and by their use broken chains may be made serviceable until it is convenient to take them to a blacksmith.

The cut represents an iron wire or rod of any desired size, bent to form a link, with flattened ends, which are spread apart so as to admit the other links which it is intended to join. When the chain is linked, the ends are hammered together, and then it will require a great force to draw them out. Blacksmiths often keep on hand similar links of various sizes, but with ends not lapping so much, for the purpose of mending chains, as they require only welding to make them thoroughly secure. The flattening of the ends is important, as it stiffens them.

Labelling Sheep.

It is very customary, in many parts of the world, to mark flocks of sheep upon the ears, as a badge of ownership. However necessary this practice is in large flocks, when sheep are liable to mix—and it is desirable to detect stray ones with the greatest ease—it is not necessary in small flocks of choice sheep, kept several years on the same farm for breeding; and besides, a mark on the wool answers all purposes of marking these flocks. Mr. H. G. White, of Middlesex County, Massachusetts, practises a very simple and commendable way of labelling and registering each of his breeding sheep, which we illustrate, (fig. 1.) Upon a copper tablet of the size of a dime, which is attached by a split, steel ring to the ear of the animal, (fig. 2,) two numbers are stamped, one that of the individual bearing the label, and the other that of its dam. A record is made at the same time in the flock register. The ring is attached to either ear, a hole being made with a shoe punch. It does not rust materially, causes no soreness, being on the under edge of the ear, and close to the head, it does not catch in bushes, is conspicuous enough, and lasts during the life of the sheep. If it be desirable to use these labels as flock marks, they may be made triangular, oval, square, diamond shaped, oblong, and of many other forms; and even two flocks with the same label might be distinguished by wearing them on the right and left ears respectively. The cost (about 3 cents per head) is very slight, considering that the mark lasts a sheep its life time, gives it a name, preserves a record of the dam, and if you will, of the year of birth.

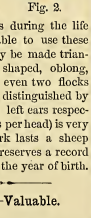

Fig. 2.

Hay and Grain Caps—Valuable.

We have yet to hear of any one who has tried home-made cloth covers for hay and grain, that would willingly give them up, among all the large number who have adopted them on our recommendation. The high price of cotton, this year, will operate against their general use, yet even with the present cost of muslin, we feel quite sure it will pay to make them. Coarse unbleached cotton cloth will answer, and the present price of 14 yards wide is only 15 to 18 cents, according to the quality and thickness. These caps, to throw over hay-cocks, and shocks of grain, often save the hay, grain and straw from rain and dew, and cure them in enough better condition to pay for the cost in a single year; while with a little care in housing, they will last many years. No farmer who values peace of mind, or good sweet hay, should be without a full supply. A cheap and easy way of making them is as follows: Take strong, unbleached cotton cloth, about forty-five to fifty-four inches wide, and cut it into squares. A larger size would hinder good ventilation of the cocks. Some persons sew into each corner a round stone weighing about eight or ten ounces, to keep the caps in place; others prefer to attach loops of stout linen cord at the corners, for pegging them down. This last method is by far the best in case of high winds. Many farmers use pegs or wires permanently attached to the caps by a cord 6 or 8 inches long. The wires are about a foot long, bent to form an eye at one end, and somewhat pointed at the other. Where wooden pins are used, they are of good stout twigs, or pine, (may be cut from shingles), ¾ to 1 inch in diameter, and 10 to 14 inches long. They may be permanently tied to the caps, or preferably, perhaps, kept separate. When the caps are spread over the cocks, a good careful man takes the pegs in a basket, goes from cock to cock, and puts in the pegs, drawing the cap down tight, and giving the peg quite an upward slant. It is much better to *tie* the cords to the caps than to sew them on, for the corners are puckered by the tying, and the sides shortened, so that there is less danger of their flapping up and taking the wind. When stones are used, it is claimed that the caps are much easier put on and taken off, and that the danger of their blowing off is slight. We prefer the attached loops, with the pins of wood by themselves. It is a job for a rainy day to make a few thousand if you wish—and if they are made of good white-pine shaved shingles, they will be easily picked out of the hay if they get in; and will even run through a hay cutter, in careless hands, without doing it any harm. The caps must never be pegged to the ground, for the hay will settle and leave the caps loose and flapping, and almost sure to blow off. When a heavy rain comes on, always visit the field and see if all the cocks maintain their conical form; if not, raise one corner of the cap and stuff a handful of hay into the crown. Of course, if a *hollow* exists any where, the rain will settle into it and run through. It is neither necessary nor desirable to have the caps made water tight, by any means. They need no hemming.

For the American Agriculturist.

Irrigation Naturally Favors Soil.

While much has been written and well written on draining the soil, but little has appeared in favor of irrigation. I think our great country is loosing much for want of attention to this subject. Having been experimenting some with irrigating, I offer my opinions about it. We have a large quantity of land in this country lying along streams, much of which, especially along large streams, is coarse, gravelly, sandy soil; on this land vegetation starts very early in the Spring and so long as rains fall once or twice a week, continues to grow; but a few days of hot sunshine dries it up. Manure helps the crop surprisingly for the first year, and then it is nearly exhausted. I once thought this was on account of the openness and looseness of the soil, but I have long since changed my opinion, I now believe the strength of the manure evaporates instead of going downwards—(am I right?) This kind of land needs no underdraining, and in short, is very poor land, seldom giving a good crop. But it is the best kind of land to improve by irrigation, that I know of. It becomes warmer when exposed to the sun than any other, and

this is one reason why irrigation improves it so much, for by flowing over it water loaded with fine particles of soil, animal and vegetable substances, the nature of the top soil is entirely changed. The gravely soil separates all the sediment by filtration, and the water passes through it clarified. The poor worthless sand is entirely changed to a beautiful loam, with the best underdraining that can be made, for the gravel remains a few inches below the surface open and porous as it was before. It is true it takes time to bring about this change, for the soil is so open you can not get the water to flow over it until it has tightened the soil. This is accomplished by degrees; every shower that raises the stream does something towards enriching the soil and filling it up, until it gradually extends over the field or meadow, when it will not require half the water needed at first.

A large portion of the land on mountainous districts, or rather what is called rolling land, is capable of great improvement by irrigation at a trifling expense. How often do we see our neighbors up the stream laboring, toiling, and hauling lime and manures of various kinds to prepare their land for a crop; and when they get it well pulverized, and the fertilizers well mixed with the soil, then comes a heavy dash of rain, often washing away a large part of the manure; and it comes rushing over our property, carrying away a portion of our labor with the rest. Now this is unavoidable, but if we could flow this water over a field laid down to grass, our land would become a kind of filter, and catch a good portion of this rich treasure as it passes by. Chemists tell us that common spring water contains in considerable quantity the ingredients needed by all growing crops—just what our land needs. If clear water contains so much nourishment for vegetation, what a large amount must the surface water from cultivated fields contain? Is it wise in us to let it pass by when we might at so small an expense enrich our soils with it? These little mountain streams are often loaded with matter from decaying leaves, etc., and thus prepared to invigorate vegetation; and as these streams start at a great elevation, they may be conveniently made to flow over a good portion of the farms below. Frenchtown, N. J.

The Potato Disease.

A writer in the Mark Lane (Eng.) Express, who has made the potato a study for years, arrives at the following conclusions respecting their diseased condition: The fungus which causes their decay is always perceptible with the microscope, and usually to the naked eye. It generally attacks the stems first, and then descends to the tubers. The same fungus is discoverable in the diseased tubers, and in the soil contiguous to them; and a like fungus has never been found on healthy haulm or tubers.

This fungus, when carefully removed from the diseased leaf and transferred to the substance of the healthy tuber, will originate the specific disease at the points of inoculation in from 4 to 8 days. Every sort of potato will, under favorable conditions, suffer; but, as a rule, the thicker the skin the less prone is the tuber to offer a timely nidus to the spores. All remedies of any practical value in checking the disease, are reconcilable with its fungoid character; and as a safeguard diseased stems and tubers should always be burned or deeply buried. Warm, humid weather, with a gentle breeze blowing from a variable point, is favorable to the invasion and rapid progress of the disease; whilst cold, dry weather temporarily checks its advance. The writer's practice for the stay of the disease consists in cutting off and removing the haulm close to the ground when diseased about half way down. Rake the soil over the lower portions of the stems, and leave them for a month. This plan is inexpensive, and usually gives a fair result, in some seasons there being only three, and in others as high as ten per cent of diseased tubers. Those not infected were of good size, mealy, and kept well.

Another good plan is to plant on ridges, and when the disease appears in the haulm, turn it down right and left, and place a little earth over the roots. The fungus is thus washed *away* from the tubers during a rain. [We give the above not to endorse them, but only as the views of one who speaks somewhat positively, and apparently from intelligent experience.—*Ed. American Agriculturist.*]

Haying Time.

In the present month, begins the great hay harvest. This is, in many respects, the most important in the whole year. Although the crop does not fill the space in the public eye, as an article of foreign commerce, which cotton does, it is yet of *greater money value.* Think of its fundamental use, the support of all kinds of farm-stock for six or seven months of the whole year. As one says: "It is, in fact, the basis of all our farm operations, the keystone which sustains them and gives them all their success. The test of a farm is the number of cattle it feeds, and the cattle in turn feed the soil." Let us, then, see to it that our crop this year is well and seasonably made and properly stored.

In preparing for this annual campaign, be sure that all other pressing labor is out of the way. This work is enough of itself to occupy one's time and thoughts while it lasts; to have other cares superadded, harrasses and perplexes one so much as to make his true and proper work very disagreeable. Get all other matters well ahead, so as to feel at ease about them. Then, see that the tools and implements are in complete order—scythes, grindstones, mowing-machines, hand-rakes, horse-rakes, pitch-forks, wagons, racks, and hay-caps. The extra hired help—is that engaged?—enough of it?—and of such a sort as to be reliable?

The best time to cut hay, is an important matter to determine. The *end* sought in gathering hay is, obviously, to cut it when it contains its most nutritive properties, viz., mucilage, starch, gluten and sugar, in the best state for their preservation. Experience shows that *that* period is when the grass is just in full flower. After this time, the fiber becomes woody and indigestible. The Cyclopædia of Agriculture says: "It has been proved that plants of nearly all sorts, if cut *when in full vigor*, afterwards carefully dried, without any waste of their nutritive juices, contain nearly double the quantity of nourishing matter which they do when allowed to attain their full growth, and make some progress towards decay." Yet, some good farmers hold that Timothy should not be cut until it passes this stage, and has nearly ripened its seed; and this chiefly for the reason that, if cut earlier, the roots are weakened and the meadows gradually destroyed. Still, as a general rule, the prevalent method of cutting grass "when in the milk," is the right one.

When hay is to be cut with scythes, the work should begin early in the day: the morning dew is a great help to the mower. There should be a liberal resting time at mid-day, and then the work resumed and carried on briskly until evening. A lunch of plain food, moistened with cold coffee or home-brewed beer, may be brought into the meadow in the middle of each forenoon and afternoon, if the hands will be discontented without it, but it is poor policy to keep the hands and the stomach both at work all the time, and three good meals are *best* for any man, however hard his work. There is enough heat in haying time without the addition of "fire-water." As to the expediency of using mowing-machines, we declare decidedly in their favor, especially on farms of considerable extent. They save time, labor, a great deal of anxiety, and in the long run, money. When the mowing machine is used, do not cut a rod before the dew is entirely off, for when the hay is cut by the machine, unless very heavy, it will need no stirring.

"Make hay while the sun shines," is a good rule, but it may be carried too far in haying time. We want the bright sunshine first to wilt the hay thoroughly; then let the drying process stop. Rake up the grass in high cocks while still hot. If rain threatens, put on the hay caps; put them on by 4 o'clock to keep off heavy dews. The grass may lie in cocks two days or less, as convenient for the farmer. On a clear day, open the cocks, about the middle of the forenoon after the ground is warm, for an airing, spreading the hay and turning once or twice for two or three hours; then haul to the barn. The practice of salting hay, at the time of storing it, is quite common, and it is applied the more abundantly when the hay is imperfectly cured. A little salt, say two or three quarts to the ton, can wisely be applied. More than this does little good, and on the whole, may be injurious.

One Cause of Drouths and Freshets.

It is plain to every observer, that our country is now more subject to drouths than it was twenty or thirty years ago. Within the last five years, we have suffered in this respect seriously. The loss to the farming community, and through it to the whole population, has been many millions of dollars. If they continue for several years more, in frequent succession, there is reason to fear that the "hard times" will pass away very slowly. Is there any natural cause of drouths, or are they sent upon us solely as special visitations of Providence for our national sins? We would not speak lightly of such visitations, but we are inclined to think that our sufferings in this particular may be traced chiefly to our own bad management. The wide destruction of our forests doubtless has something to do with the production of drouths, and of those destructive floods or "freshets" which are becoming alarmingly frequent.

If the country is widely denuded of its trees, the land is more exposed to the burning rays of the sun, and to the winds which cause a very rapid evaporation. Then, too, forest-trees are so many pumps to suck up moisture from the depths of the earth, and to diffuse it through their leaves into all the surrounding atmosphere. From thence it falls upon the surface of the ground. Perhaps some of our readers have amused themselves with making estimates of the amount of water evaporated from the leaves of a single tree, and then of a large forest, in a single day. To one who has never thought about it, the subject is one of great interest. All readers of history know that many of the rivers and streams of the old world, which once were

wide and deep, have now shrunk into much smaller dimensions; from what cause, can any one tell, if not that the hills and mountains are now almost entirely bereft of trees? Drouths prevail all over the Eastern continent, with increasing severity; and scientific and observing men everywhere proclaim that this is owing chiefly to the cause of which we now speak.

Valleys and low-lands, and fertile plains should of course be cleared of trees and devoted to farms and gardens; but at least the rocky hills and mountains should not be shorn of their leafy honors. Let the trees stand sacred from the desolating ax, all along our hights, to break the fury of storms, and to condense and bring down the useful vapors of the clouds upon our fields and into our springs and streams. It is high time that the older States of the Union began to move in this matter, either regulating the destruction of our old forests, or encouraging the growth of new. We believe that some wholesome laws touching this matter would both secure our posterity a good supply of lumber, and a good degree of exception from drouths.

All that individuals can do in this matter is to preserve their own forest land in just proportion, and by underdraining, thus deepening the soil and giving it a porous spongy character, render the land capable of absorbing and retaining as large a quantity as possible of the water that falls upon it, instead of allowing a large portion to flow off as is now generally the case. Our State Legislatures might, we think, with great propriety remit the taxes for 20 years on all land devoted to high forest, (not *low* woods for charcoal and hoop poles,) and tax land which might but does not carry a good growth of high or low woods at the rate its value would warrant if properly improved. FORESTER.

Improvement of Pine Plains.

At the mention of the words "pine plains," whose thoughts do not at once recur to such regions as Saratoga and Schenectady counties, some portions of Connecticut, Long-Island, New-Jersey, Virginia, and indeed other large sections of the country? Can anything be done to improve this land, much of which is like an ash-heap, and all of it comparatively sterile? Experience shows that it can be ameliorated, yet not without labor skillfully applied.

In many cases this soil has an underlying stratum of marl, which contains most of the ingredients necessary to restore its fertility. And wherever this marl does not lie so near at hand, it can generally be obtained from other quarters at no great expense. We have been informed of its being applied to barren, sandy knolls, which produced no sort of vegetation whatever, and which blew about in the wind; the result was that these knolls yielded a crop superior to that on any other part of the field; these other portions being in good ordinary condition, but receiving no sort of manure. The application of marl serves to give tenacity and consistency to the soil, and prepares it to profit by the vegetable and other manures which should be applied in routine afterwards.

The frequent practice of renovating these lands by clovering and plastering, is excellent and economical. The objection sometimes made, that the clover roots are thrown out by frost, may be removed, partially at least, by thorough harrowing after seeding, and then following with the roller. The usefulness of this last named implement on light soils, is not yet so fully appreciated as it should be.

For lands of this sort, the best rotation is: clover turned in for winter wheat; Indian corn; and barley, oats, or spring wheat with which clover and timothy grass should be sown. Always let the roller follow the seeding. It crushes lumps, fills up interstices, makes the surface compact and smooth, hastens the germination of seed, and causes the roots to strike deep in the soil. The next year after seeding the ground to clover, apply a good dressing of plaster, and devote the land to a hay crop. Next year, plaster again, and let the clover grow until about the last of June, when the sod may be turned under and the land devoted to a grain crop. As to the best method of preparing the ground for wheat, farmers do not quite agree. After the sod has once been turned under, some cross-plow and thoroughly break up the turf before seeding. Others do not disturb the inverted sod, but sow their seed on top of the furrows, harrowing it in and rolling smooth. Farmers are not all agreed whether wheat or corn should follow clover, nor whether the sod should be broken up in Fall or Spring just before planting. This rotation of crops should be accompanied with such annual dressings of marl, ashes, plaster, and such other manures as can be obtained. Muck or swamp mud strengthen the texture and enrich the soil.

For the American Agriculturist.

Demolish Your Fences.

The advice is somewhat radical for an orthodox conservative journal, you say. But perhaps the reader will not differ from the writer very much, when he comprehends our meaning fully. The most conspicuous feature of the northern farm, is its fencing. It must have been a ruling passion with our fathers, and one groans in the spirit to think of the weary days and months they spent in laying stone wall. We have before us, as we write, a little patrimony of twelve acres, cut up into lots of one acre, ¾ of an acre, 1¼ acres, 1½ acres, 2 acres, 1 acre, and the only reason why the balance was not still further divided was the fact that it is a swamp where stones were not convenient for building. This subdivision of land is only a little in excess of what prevails on a large class of farms, particularly those in rough or rocky lands. Farms of one, two, and three hundred acres are numerous, on which there is not a cultivated field of more than ten acres; while one, two, and three acre lots are numerous. Nothing but the pastures were left of tolerable size, and these only because they were too rocky or wet even to admit of plowing. I know of a farm in Connecticut of one hundred and sixty acres that is cut up into twenty five separate lots, including woodland and pasture. Excluding these, the fields would not average four acres each. The fencing upon this farm is much like that of the farms in the neighborhood, and is only mentioned because I happen to be acquainted with it. Taking only one half this as a fair average of the fencing of the improved land in this and the adjoining States, it makes a very formidable item in the expense of the farm. The fact is one that will not be disputed, that there are a great many pretty good farms in New-England, and New-York, at any rate, that will not sell for what the fences cost. An estimate of the cost of fences in the State of Ohio, made by the Board of Agriculture, amounts to 115,000,000 dollars. What the motives of our fathers were, in encumbering the soil with so much fence, except where the land was to be cleared of stones, it is difficult to conceive. If the idea was to get rid of the surface stones, they signally failed, for what can be more in the way of cultivation than a stone wall on the four sides of every acre of land?

Whatever the objects in view, they were no compensation for the manifold evils of small inclosures. The yearly expense of keeping these fences in repair is enormous. It is estimated that it equals the whole cost of renewal once in 15 years. The cheaply built stone wall is soon thrown out of line by the frosts, and is thrown down. The stones often have to be put up every Spring, when the farmer wants his time for other purposes. They hinder cultivation more than any one would suppose, who had not practical acquaintance with the evil. The loss of time to the man and team in turning round at the ends of an acre lot in plowing, harrowing, cultivating, mowing, etc., is very great. The loss of land is also considerable. If a wall is only four feet wide inclosing an acre, yet counting but half, it will occupy six square rods, or about four per cent, making one acre in twenty five. But beside the land actually taken up by the wall, there is a space each side difficult to plow. I have no hesitation in saying that three-fourths of our stone walls are a nuisance that call loudly for abatement. They are an eyesore upon the farm, and as much a blot upon our husbandry as they are upon the beauty of our landscape.

But what shall be done with these walls, if we come to this sweeping conclusion? That of course must depend somewhat upon circumstances. Where the land is worth forty dollars or more an acre for cultivation, I would say use them to construct stone drains. This will put them out of sight, and at the same time put them to a good use where they will pay a large interest upon the money spent in sinking them. A drain constructed with this object in view makes a market for a great quantity of stones; it carries off all surface water, and permanently benefits the soil for rods on each side. A case recently fell under my notice in which one of our best cultivators had dug ditches 3 feet deep, and 4 feet wide at the bottom, and made them the recipients of an immense quantity of stones. The *increased* yield of grass he estimates as paying annually the interest on $300 per acre over and above the extra expenses of cutting and curing. But there are a great many poor farms worth on an average not more than ten dollars an acre, and the poorest part of them not worth five. What shall be done with the fences in this case? To sink the walls for underdraining would cost four or five times as much as the land is worth. If I owned such land I would either sell the most of it, or hire capital to improve it. In its present condition it hardly pays taxes, and the expense of working. We might remove the old fences, and underdrain thoroughly, as far as we went. Clean smooth fields embracing about one-fourth of the whole farm are the desirable thing in husbandry. With the exception of inclosures for the garden and orchard, and a small field or two near the barn, we would demolish all other fences as fast as we could.

The expense of a boy and dog, or a regular herdsman on large farms, is not by any means so great as that of building and maintaining fences as we do throughout this country, to say nothing of the gain in land and other advantages. Cattle and sheep constantly herded and attended by some person, are docile to a surprising degree, and the ability to regulate their feeding so as to accomplish a saving of feed, by making their feed regularly over one part of the pasture at a time, of itself is said to pay the expense of the herdsman. CONNECTICUT.

TENDING GEESE.—FROM A PAINTING BY E. MEYERHEIM.—*Engraved for the American Agriculturist.*

Treatment of Strawberries in June.

Next after clean cultivation, they want water or liquid manure. If the soil is a light loam, gravelly, or artificially drained, it can hardly have too much water. The plants are either in full flower, or full of berries ripening from day to day, and they need abundant supplies of moisture. The days are at their greatest length and the sun shines in its greatest splendor.—The evaporation in one of these long bright summer days is immense, and a drouth just in the critical time often diminishes the strawberry crop one half or more. Mulching is of great advantage as it retains moisture as well as keeps the fruit clean. We can only get the largest berries with abundant watering. For the flavor we are somewhat dependant upon the sunshine. So great is the advantage of watering that we think it would often pay, even in field culture, to have an apparatus for the purpose, like the water carts for sprinkling city streets. In the garden it is entirely practicable, with a garden engine, hydropult, or common watering-pot.

One of the best methods to get plants for a new bed is to start them in thumb pots, as early in the month as practicable. An old plant is surrounded with these pots, and the runners strike their roots into them, and form vigorous plants, which may be transferred to the new bed about the first of August. The roots are perfect, and the plants are not put back. Nearly a full crop may be expected of such plants the first season after the bed is prepared. Of course, old plants that are used for propagating, can not be expected to do much else. A few of the plants may be struck in four inch pots, and kept for the conservatory or parlor in the Winter. Both the flowers and the fruit are ornamental.

The Raspberry.

Cultivators of limited experience are not so generally successful with this fruit, as with the strawberry. All the finer varieties are either of foreign origin, or seedlings of such sorts. Even if not tender or half hardy, they are certain to do much better with a few inches of earth over them, during the winter. Though this is very little trouble, involving less than a half dollar's expense in an ordinary garden, most people will not take it. (After years of trial we have abandoned both the native red and the black. We have many sorts, larger and better every way.)

Others, and they are the great majority, leave the canes to take care of themselves. They are generally planted by the side of a fence or stone wall, where hoeing is inconvenient, if it were the policy to practice it. The old canes are not removed, the new ones are not thinned, and the stools all run together; and between the weeds, grass, and excessive growth of wood, there is little or no fruit, and an utter want of cultivation.

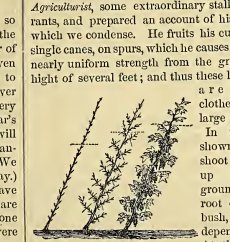
In other cases the leaves are annually attacked by insects about fruiting time, and the young shoots are stunted, and the fruit is imperfect. It is a clear case, that we can not have fine raspberries without some trouble—a little of it at every season of the year.—Just now, the insects must be attended to, or the crop is injured, if not ruined for this season and the next. We have tried nothing quite equal to whale oil soap for all the varieties of worms that attack the leaves. It should be applied in a dilute state, say four pounds to a barrel of water, or the remedy may prove worse than the disease. It is best applied with a garden syringe, though a watering pot with a fine rose will answer. A strong decoction of tobacco is also excellent, and will destroy most of these pests. We have always found it of great service to water raspberries while fruiting. They will drink in soapsuds, and all liquid manures as greedily as a grape vine, and are as much benefitted by it.

There are various expedients for supporting the canes. Some tie them to a single rod or pole driven down by the side of the stool, and where the leaves are already out this is the best method. A better way, earlier in the season, is to tie the tops of the canes in adjacent stools together, in the form of an arch. This arrangement is quite ornamental and is as convenient for picking as any. But the best arrangement is to tie the canes to a wire trellis. Posts of any convenient size, 4 or 5 feet high, are set about 12 feet apart, in the row with the stools. Two number 10 wires are now fastened about 18 inches apart on the posts, and the canes are spread out in fan shape and tied to the wires. This is ornamental and at the same time, gives the plants the most air and sunlight. The old canes are to be removed as soon as the bearing is over, and five or six only of the new ones left to grow.

"Espalier" or Wall Training of Fruits.

Whoever has not practised the close pruning and training of fruit trees upon trellises or walls shrinks from attempting it, as from a great labor likely to be unremunerative. But whoever begins, even in a very humble degree, becomes almost uniformly an advocate of the practice.

The Currant, is probably the easiest of all fruits to experiment upon, and from practice with it the general principles of close pruning may be learned, while the results are most gratifying. Last year George H. Hite, of Morrisania, N. Y., placed upon the exhibition tables of the *Agriculturist*, some extraordinary stalks of currants, and prepared an account of his process, which we condense. He fruits his currants on single canes, on spurs, which he causes to form of nearly uniform strength from the ground to a hight of several feet; and thus these long canes are perfectly clothed with large fine fruit. In fig. 1 is shown a strong shoot thrown up from the ground at the root of an old bush, or an independent cane. At the end of the first season, it is cut back one *third*. If attached to a trellis or otherwise made to incline the next spring, the buds will all break uniformly from top to bottom. If it stands upright, the sap will flow chiefly to the uppermost buds. When the buds have grown a few inches, as shown at fig. 2, they are pinched off to leave spurs about an inch long, as shown enlarged in fig. 4. These will develop a rosette of buds at the base of each, which are the fruit buds for the next season. The terminal bud at the top of the cane is left, and will have stretched upward considerably. In the autumn shorten it in one fourth of its growth; and the succeeding years still less. The next year the cane will bear full, as shown at 3; and if the soil be good, and the bush has air and light, the fruit will be large and fine. The spurs must be prevented from growing long, and they will bear year after year. Several such canes may be grown from an old root, while the old bush, by stopping in the spurs, will bear much better until the new canes are ready for full bearing. Currants may be set out about a foot apart, two or three such canes grown upon each root, and thus in small compass yield an immense quantity of fruit. (Fig. 1 is proportionately too long.)



1. 2. 3.

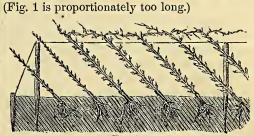


Fig. 5.

Fig. 4.

Apples and Pears may be subjected to very similar treatment, being planted close, or further apart, according to the system followed or the hight to which they are wanted to grow. Fig. 5 shows an experiment conducted by Mr. F. Otto, in our own garden, which promises success. Dwarf apples are planted one foot apart, and trained to a rod 18 inches above ground. (A wire is perhaps preferable). The inclined position causes them to break throughout their length quite uniformly, and to secure this a greater or less degree of inclination or curving may be given. The spurs if kept closely pinched in, form fruit buds. The tops when they have reached the hight desired are allowed to branch somewhat, and the branches are inarched or grafted together by approach, so that after a few years the fruit-bearing hedge thus formed will be self supporting and substantial and ornamental. Keeping fruit trees under this close control enables us to secure healthy, well developed fruit buds on the spurs, and to protect easily the tender kinds from frosts. Peaches, plums, and berries, do very well upon walls or trellises.

Rout the Curculio.

This enemy of the plum can be routed without the old and laborious process of jarring the trees, and gathering the insects upon sheets. The following remedy has been several years before the public, and has the recommendation of Mr. Cummings, and some of our best pomologists. The writer has used it with success and now feels as sure of the plum crop as of pears. To one pound of whale oil soap, add four ounces of flowers of sulphur. Mix the mass thoroughly with a spatula or knife, and dissolve in about twelve gallons of water, stirring it well.

To one half peck of quick lime, add four gallons of water and stir well together. When fully settled, pour off the transparent lime water, and add it to the soap mixture. Add to the same, also, say four gallons of tolerably strong tobacco water. Apply this mixture when thus incorporated, with a garden syringe, to your plum or other fruit trees, so that the foliage shall be well drenched. If no rains succeed for three weeks, one application will be sufficient. It should be repeated after rains until the stone is hardened. When the plum is about the size of a pea is the best time to apply it, but it is effectual upon all plums not yet stung at any stage of their growth. This mixture is good for cherries, and all fruits troubled with insects. *

"Celery as a Field Crop."

To the Editor of the American Agriculturist.

As the writer of the article under the above heading in the March *Agriculturist*, I am induced to reply to the doubt you express, that under the treatment described the celery would not be tender. Permit me to assure you that the very reverse is the case. Celery earthed up in the usual way, when in full growth, tastes much stronger and is far less crisp than when blanched by the trench system. This we find to our cost, as our workmen, when preparing it for market, devour it in great quantities in the Winter, while they rarely touch it in the Fall when it has to be blanched while in the growing state. The principle in blanching celery by the trench system is nearly similar to that practiced in forcing Sea Kale and Rhubarb, and all who have practised it know the high degree of crispness and tenderness attained by growth when excluded from light (and partially from air), as is the case in this method of blanching celery, or forcing of Sea Kale and Rhubarb. I have grown upwards of 15 acres—nearly half a million roots—of celery annually for the last ten years, and in that time have preserved it in various ways, but in no way so safely and cheaply as by the system described in the March *Agriculturist*. In fact nineteen-twentieths of all the celery sold in the New-York markets is thus blanched; all my neighbors for miles around, practice this method exclusively. A JERSEY MARKET GARDENER.

The White Kidney Bean.

"You don't know beans," is a term of reproach much more generally deserved than the world supposes. We have gone through the whole catalogue of beans, pole and dwarf, China, Scipio, case-knife, asparagus, wild goose, marrowfat, cranberry, etc., and have never found any thing to compare with the white kidney for baking. The Lima is decidedly better as a table vegetable, and for making succotash. But the Lima is a pole bean, and is not a sure crop in all parts of the north, while the kidney is as easily raised as the common white field bean, and will mature where any bean will. It should have a good soil, and we will say here, in passing, that we have never known it to run to vines, planted in the richest soil, or at any time of the moon. It is not quite as early as the China, but bears far more abundantly. It is excellent as a snap bean, but baking alone brings out all its excellences. It is easily cooked, very delicate, and thin skinned, and entirely free from the strong taste which marks most pole beans. It is not very widely known, but is so far appreciated that it always bears the highest price in market. It is well known in the cities and among epicures, and ought to be better known among villagers and farmers. We suspect the majority of our readers are still strangers to a perfect dish of baked beans.

Spontaneous Vegetation—Query.

To the Editor of the American Agriculturist.

I have been pleased and profited by your remarks on spontaneous vegetation, and believe them founded in scientific truth. But a few facts have come to my knowledge, lately, which are noteworthy: I send the nuts to your learned readers to crack. Some years ago, a low piece of ground in the suburbs of Albany was raised by dirt brought in by railway trucks from a distant hill side—a hill which had not been disturbed perhaps for centuries. Yet, no sooner had this "made land" been leveled off and allowed to stand for a few weeks, than it produced a rank growth of weeds and grasses. Now, did this vegetation spring from an original principle in the soil, or from seeds, perhaps a thousand years old, buried in that hill?

After the great fire in London, in 1666, the entire surface of the destroyed city became green in Summer with multitudes of a cruciferous plant—the *Sisymbrium iris* of Linnæus. How came they there? Did the fire beget them?

When a salt spring occurs far from the seashore, numerous plants peculiar to maritime regions, are often found in the neighborhood. Does salt air evoke these plants from the soil?

If a lake or pond happens to dry up, the bottom will exhibit a vegetation unlike that of the banks or adjoining fields. Whoever cracks the nuts, let him report. SCHOLASTICUS.

For the American Agriculturist.

The Best Time to Prune.

An old clergyman is quoted as defining this time to be "when your knife is sharp." He was certainly half right, for a smooth clean cut is very essential to the healing of the wound. But there is very great difference in the healing of wounds on account of the season in which they are made. Pruning done in March and April, especially if large limbs are removed, often injures an orchard for life. The sap oozes from all the pores and runs down upon the bark, discoloring and oftentimes destroying it—called scalding. Without other protection, decay begins, and in a few years you have a hollow limb.

We like the month of June for pruning better than all others. If the work is done soon after the new wood begins to form, the wounds made by the removal of small limbs will be nearly covered over the same season they are made. The leaves make such a demand upon the wood for sap that none of it escapes from the wounded pores. It is also a favorable time for thumb pruning. By watching the growth of the shoots upon young trees they may be brought into symmetrical shape without much use of the knife.

JONATHAN.

Raising Peaches.

To grow them from seed, bury the pits in shallow boxes in alternate layers of sand or light earth, and expose them where they shall get a good freezing. This will crack the shell and favor their germination. Those which do not get cracked by the frost, must be broken with a hammer. The best soil for the peach is a rich warm, gravely loam. Plow and harrow into fine condition for working. Lay off the drills three feet apart, and plant the seeds ten inches asunder in the drill, and about an inch deep. This should be done as early in the Spring as the weather will permit. When the shoots appear above ground, go through the rows, and with hand and hoe give them a good weeding, otherwise they will get smothered. When about six inches high, put a cultivator into the rows, using a very careful horse, and then follow with the hoe. This will expedite the growth of the seedlings: in ordinary cases, the planter will have no reason to complain of the slow progress of his little trees. In many cases, budding is not resorted to; it is thought enough to grow new trees from good seed of good parent trees. But, by all means, avoid seed from trees which have the Yellows or any other disease. If pains is taken, one will get good fruit, though it will vary somewhat from the stock. But when it is desired to propagate any known varieties, budding must be resorted to. When this is done, the operation should be performed on the larger seedlings, in the latter part of the first season; say, from the first to the middle of September. As the peach grows quite late into the Fall, this will give the bud time to unite well with the stock before Winter. Next Spring, before growth begins, head back the stock; the bud will soon start, and grow several feet in the season. It will be ready to transplant in the Fall.
